Introduction: heavy ion collision in pictures¹

- Initial state, hard scatterings
- Thermalization
- Hydrodynamic expansion
 - ▶ Quark-gluon plasma
 - ▶ Phase transition
 - ▶ Hadron Gas
 - ▶ Chemical freeze-out
- Kinetic stage

Typical size
10 fm \propto
 10^{-14} m

Typical lifetime
10 fm/c \propto
 10^{-23} s

● (kinetic) freeze-out

1 taken from event generator

Relativistic viscous hydrodynamics

$$\begin{cases} \partial_\mu T^{\mu\nu} = 0 \\ \partial_\mu N^\mu = 0 \end{cases}$$

$$T^{\mu\nu} = \varepsilon u^\mu u^\nu - (\rho + \Pi) \Delta^{\mu\nu} + q^\mu u^\nu + q^\nu u^\mu + \pi^{\mu\nu}$$

$$N^\mu = n \cdot u^\mu + v^\mu$$

+equation of state (EoS) $p = p(\varepsilon, n)$

where $\Delta^{\mu\nu} = g^{\mu\nu} - u^\mu u^\nu$ is the projector orthogonal to u^μ ,
(in the fluid rest frame where $u^\mu = (1, 0, 0, 0) \Rightarrow \Delta^{\mu\nu} = \text{diag}(0, -1, -1, -1)$)

q^μ is the heat flux

$\pi^{\mu\nu}$ and Π are the shear stress tensor and bulk pressure

v^μ is a (baryon, etc) charge diffusion

$q^\mu = \pi^{\mu\nu} = \Pi = v^\mu = 0 \Rightarrow$ ideal fluid.

Definition of u^μ

Since in general case there is no common direction for energy-momentum flow and particle flow,

1. Landau definition (flow of energy):

$$u_L^\mu = \frac{T_\nu^\mu u_L^\nu}{\sqrt{u_L^\alpha T_\alpha^\beta T_{\beta\gamma} u_L^\gamma}} \quad \Rightarrow \quad q^\mu = 0$$

2. Eckart definition (flow of conserved charge)

$$u_E^\mu = \frac{N^\mu}{\sqrt{N_\nu N^\nu}} \quad \Rightarrow \quad v^\mu = 0$$

! we adopt Landau definition (Eckart frame is undefined when $n = 0$)

Relativistic Navier-Stokes

from the second law of thermodynamics

In ideal hydrodynamics:

$$\begin{cases} \partial_\mu T^{\mu\nu} = 0 \\ \partial_\mu N^\mu = 0 \end{cases} \Rightarrow \partial_\mu S^\mu = \partial_\mu (s u^\mu) = 0$$

In viscous hydrodynamics:

$$\partial_\mu S^\mu > 0$$

$$T \partial_\mu S^\mu = \dots = -u_\nu \partial_\mu \delta T^{\mu\nu} = \dots = \pi^{\mu\nu} \cdot \langle \Delta^{\mu\lambda} \partial_\lambda u^\nu \rangle - \Pi \cdot \partial_\mu u^\mu$$

Then, $\partial_\mu S^\mu > 0$ if

$$\begin{cases} \pi^{\mu\nu} = 2\eta \langle \Delta^{\mu\lambda} \partial_\lambda u^\nu \rangle \\ \Pi = -\zeta \partial_\mu u^\mu \end{cases}$$

These constitutive equations correspond to relativistic generalization of Navier-Stokes equations.

Relativistic Navier-Stokes

Causality problems:

For small perturbations around uniform flow:

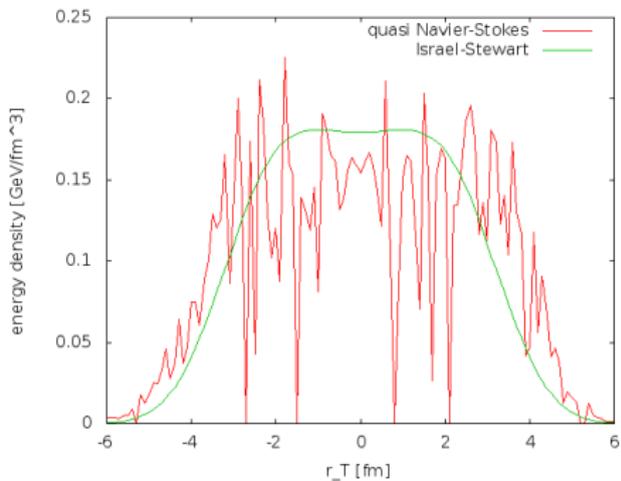

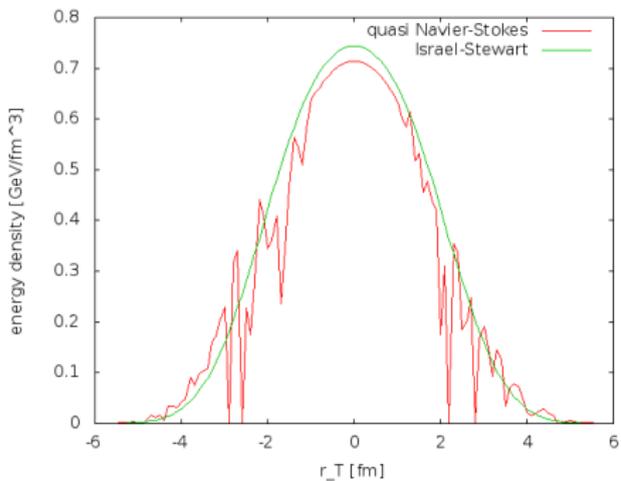

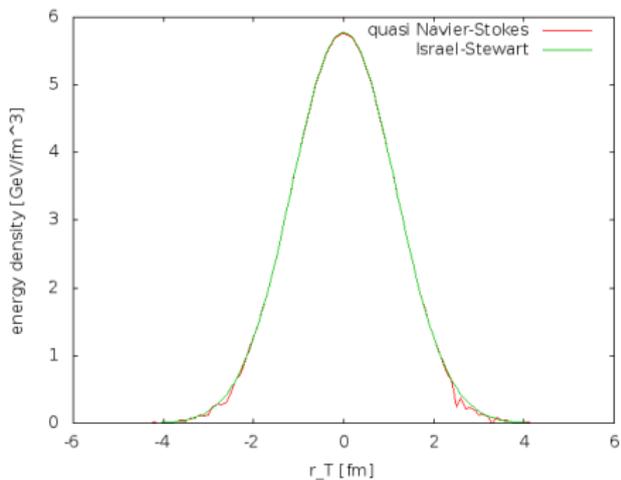

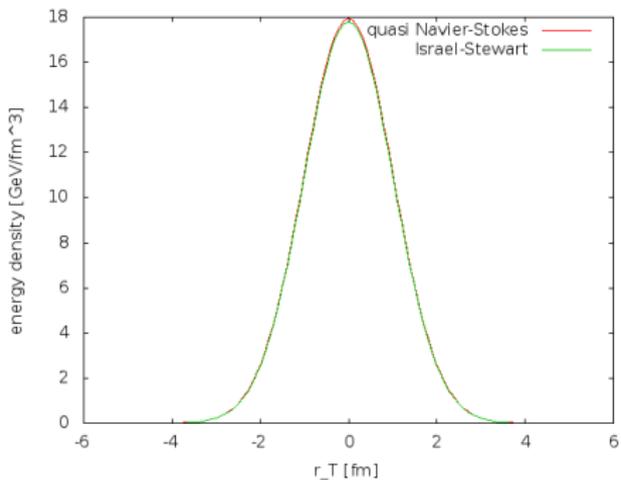

$$\partial_t \delta u^y - \frac{\eta}{\varepsilon + p} \partial_x^2 \delta u^y = 0$$

Diffusion speed for wavemode k :

$$v_T(k) = 2k \frac{\eta}{\varepsilon + p} \rightarrow \infty, \quad k \gg 1$$

Such paradox is a consequence of an insufficient description of the thermodynamical state in nonequilibrium (Müller, 1968)

Acausality \rightarrow **instabilities** (Hiscock, Lindblom '1985)

Second-order theory: Israel-Stewart formalism

Entropy current

$$S^\mu = sU^\mu = s_{\text{eq}}U^\mu - (\beta_0\Pi^2 + \beta^2\pi^{\alpha\beta}\pi_{\alpha\beta})\frac{U^\mu}{2T}$$

Then, the requirement $\partial_\mu S^\mu > 0$ leads to

$$\langle D\pi^{\mu\nu} \rangle = -\frac{\pi^{\mu\nu} - \pi_{\text{NS}}^{\mu\nu}}{\tau_\pi} - \frac{1}{2}\pi^{\mu\nu} \left(\partial_\lambda U^\lambda + D \ln \frac{\beta_0}{T} \right)$$

$$D\Pi = -\frac{\Pi - \Pi_{\text{NS}}}{\tau_\Pi} - \frac{1}{2}\Pi \left(\partial_\lambda U^\lambda + D \ln \frac{\beta_2}{T} \right)$$

where $D \equiv U^\mu \partial_\mu$, $\tau_\pi = 2\eta\beta_2$, $\tau_\Pi = \zeta\beta_0$, and Navier-Stokes values for the viscous components:

$$\pi_{\text{NS}}^{\mu\nu} = 2\eta\sigma^{\mu\nu} = \eta(\Delta^{\mu\lambda}\partial_\lambda U^\nu + \Delta^\nu\lambda\partial_\lambda U^\mu) - \frac{2}{3}\eta\Delta^{\mu\nu}\partial_\lambda U^\lambda$$

$$\Pi_{\text{NS}} = -\zeta\partial_\lambda U^\lambda$$

The solutions are stable, provided that τ_π, τ_Π are big enough
(for example, $\tau_\Pi > \frac{3}{2}\frac{\zeta}{sT}$ from stability condition around hydrostatic state*)

The scheme

Coordinate transformations

Milne coordinates

The coordinate system is defined as follows:

$$0) \tau = \sqrt{t^2 - z^2}$$

$$1) x = x$$

$$2) y = y$$

$$3) \eta = \frac{1}{2} \ln \frac{t+z}{t-z}$$

$$g^{\mu\nu} = \text{diag}(1, -1, -1, -1/\tau^2)$$

Nonzero Christoffel symbols are:

$$\Gamma_{\tau\eta}^{\eta} = \Gamma_{\eta\tau}^{\eta} = 1/\tau, \quad \Gamma_{\eta\eta}^{\tau} = \tau$$

$$T^{\mu\nu} = (\varepsilon + p)u^{\mu}u^{\nu} - p \cdot g^{\mu\nu}, \text{ where}$$

$$u^{\mu} = \left\{ \cosh(\eta_f - \eta) \cosh \eta_T, \sinh \eta_T \cos \phi, \sinh \eta_T \sin \phi, \frac{1}{\tau} \sinh(\eta_f - \eta) \cosh \eta_T \right\}$$

$$\text{(cf. } u_{\text{Cart}}^i = \left\{ \cosh(\eta_f) \cosh \eta_T, \sinh \eta_T \cos \phi, \sinh \eta_T \sin \phi, \sinh(\eta_f) \cosh \eta_T \right\})$$

EM conservation equations are

$$\partial_{;v} T^{\mu\nu} = 0$$

or

$$\mu = 0: \quad \partial_v T^{\tau\nu} + \tau T^{\eta\eta} + \frac{1}{\tau} T^{\tau\tau} = 0$$

$$\mu = 1: \quad \partial_v T^{x\nu} + \frac{1}{\tau} T^{x\tau} = 0$$

$$\mu = 2: \quad \partial_v T^{y\nu} + \frac{1}{\tau} T^{y\tau} = 0$$

$$\mu = 3: \quad \partial_v T^{\eta\nu} + \frac{3}{\tau} T^{\eta\tau} = 0$$

EM conservation equations are

$$\partial_{;v} T^{\mu\nu} = 0$$

or

$$\mu = 0: \quad \partial_v T^{\tau\nu} + \tau T^{\eta\eta} + \frac{1}{\tau} T^{\tau\tau} = 0$$

$$\mu = 1: \quad \partial_v T^{xv} + \frac{1}{\tau} T^{x\tau} = 0$$

$$\mu = 2: \quad \partial_v T^{yv} + \frac{1}{\tau} T^{y\tau} = 0$$

$$\mu = 3: \quad \partial_v T^{\eta\nu} + \frac{3}{\tau} T^{\eta\tau} = 0$$

Additional transformations:

$$\begin{aligned} T^{\mu\eta} &\rightarrow T^{\mu\eta}/\tau, \quad \mu \neq \eta, \\ T^{\eta\eta} &\rightarrow T^{\eta\eta}/\tau^2 \end{aligned}$$

$\Downarrow\Downarrow$

$$\partial_v(\tau T^{\tau\nu}) + \frac{1}{\tau}(\tau T^{\eta\eta}) = 0$$

$$\partial_v(\tau T^{xv}) = 0$$

$$\partial_v(\tau T^{yv}) = 0$$

$$\partial_v(\tau T^{\eta\nu}) + \frac{1}{\tau}\tau T^{\eta\tau} = 0$$

Conservative variables are

$$Q^\mu = \tau \cdot T^{\tau\mu}$$

The exact expressions for **evolutionary equations** for viscous corrections:

$$\gamma(\partial_t + v_i \partial_i) \pi^{\mu\nu} = -\frac{\pi^{\mu\nu} - \pi_{\text{NS}}^{\mu\nu}}{\tau_\pi} + I_\pi \quad (1)$$

$$\gamma(\partial_t + v_i \partial_i) \Pi = -\frac{\Pi - \Pi_{\text{NS}}}{\tau_\Pi} + I_\Pi \quad (2)$$

where the extra source-terms are:

$$I_\pi = -\overbrace{\frac{4}{3} \pi^{\mu\nu} \partial_{;\gamma} u^\gamma}^{\text{extra IS terms}} - \overbrace{[u^\nu \pi^{\mu\beta} + u^\mu \pi^{\nu\beta}] u^\lambda \partial_{;\lambda} u_\beta}_{\langle D\pi^{\mu\nu} \rangle = \dots} + I_{\pi, \text{geom}}(\pi) \quad (3)$$

$$I_\Pi = -\frac{4}{3} \Pi \partial_{;\gamma} u^\gamma + I_{\Pi, \text{geom}}(\Pi) \quad (4)$$

and $\partial_{;\mu} u^\nu = \partial_\mu u^\nu + \Gamma_{\mu\lambda}^\nu u^\lambda$ is covariant derivative.

Closer to numerics:

$$\partial_\mu (T_{\text{id}}^{\mu\nu} + \delta T^{\mu\nu}) = S^\nu, \quad S = \text{geometrical source terms}$$

$$\partial_\tau \underbrace{(T_{\text{id}}^{\tau i} + \delta T^{\tau i})}_{Q_i} + \partial_j \underbrace{(T^{ji})}_{\text{id.flux}} + \partial_j \underbrace{(\delta T^{ji})}_{\text{visc.flux}} = \underbrace{S_{\text{id}}^\nu + \delta S^\nu}_{\text{source terms}}$$

Finite-volume realization:

$$\frac{1}{\Delta\tau} (Q_{\text{id}}^{n+1} + \delta Q^{n+1} - Q_{\text{id}}^n - \delta Q^n) + \frac{1}{\Delta x} (\Delta F_{\text{id}}^{n+1/2} + \Delta \delta F^{n+1/2}) = S_{\text{id}}^{n+1/2} + \delta S^{n+1/2}$$

²Makoto Takamoto, Shu-ichiro Inutsuka, J.Comput.Phys. 230 (2011), 7002 

Closer to numerics:

$$\partial_\mu (T_{\text{id}}^{\mu\nu} + \delta T^{\mu\nu}) = S^\nu, \quad S = \text{geometrical source terms}$$

$$\partial_\tau \underbrace{(T_{\text{id}}^{\tau i} + \delta T^{\tau i})}_{Q_i} + \partial_j \underbrace{(T^{ji})}_{\text{id.flux}} + \partial_j \underbrace{(\delta T^{ji})}_{\text{visc.flux}} = \underbrace{S_{\text{id}}^\nu + \delta S^\nu}_{\text{source terms}}$$

Finite-volume realization:

$$\frac{1}{\Delta\tau} (Q_{\text{id}}^{n+1} + \delta Q^{n+1} - Q_{\text{id}}^n - \delta Q^n) + \frac{1}{\Delta X} (\Delta F_{\text{id}}^{n+1/2} + \Delta \delta F^{n+1/2}) = S_{\text{id}}^{n+1/2} + \delta S^{n+1/2}$$

now, a small trick:

$$\frac{1}{\Delta\tau} (Q_{\text{id}}^{n+1} + \delta Q^{n+1} - \underbrace{Q_{\text{id}}^{*n+1} + Q_{\text{id}}^{*n+1}}_{=0} - Q_{\text{id}}^n - \delta Q^n) + \frac{1}{\Delta X} (\Delta F_{\text{id}} + \Delta \delta F) = S_{\text{id}} + \delta S$$

Then, split the equation into two parts²:

$$\frac{1}{\Delta t} (Q_{\text{id}}^{*n+1} - Q_{\text{id}}^n) + \frac{1}{\Delta X} \Delta F_{\text{id}} = S_{\text{id}} \quad (5)$$

$$\frac{1}{\Delta t} (Q_{\text{id}}^{n+1} + \delta Q^{n+1} - Q_{\text{id}}^{*n+1} - \delta Q^n) + \frac{1}{\Delta X} \Delta \delta F = \delta S \quad (6)$$

²Makoto Takamoto, Shu-ichiro Inutsuka, J.Comput.Phys. 230 (2011), 7002

The solution then proceeds in two stages:

1a) Q_{id}^{*n+1} is obtained by evolving only the ideal part (5) of energy-momentum tensor over the full timestep Δt , which is done accurately using Godunov method: rHLL flux + MUSCL + predictor-corrector schemes

$$\Rightarrow \begin{aligned} \partial_\tau u^v &\simeq \frac{u^{*(n+1),v} - u^{n,v}}{\Delta \tau} \\ \partial_x u^v &\simeq \frac{u_{k+1}^{*(n+1),v} - u_{k-1}^{*(n+1),v}}{2\Delta x} \end{aligned}$$

1b) Advection-type evolutionary equations for $\pi^{\mu\nu}, \Pi$ are solved with 1st order upwind scheme. Velocity gradients for Navier-Stokes values of $\pi^{\mu\nu}, \Pi$ etc. are taken from above.

2) $Q_{id,j}^{n+1} + \delta Q_i^{n+1} = Q_{full}^{n+1}$ is obtained from Eq. (6) evolving over the full timestep Δt with viscous fluxes/sources ONLY.

*The initial condition for stage 2 is $Q_{ini} = Q_{id}^{*n+1} + \delta Q^n$, the first term obtained from the solution of the stage 1.

test #0: 0+1D

comparison with known analytical solution with viscosity in Navier-Stokes limit

Energy conservation: $\partial_\nu T^{\tau\nu} + \tau T^{\eta\eta} + \frac{1}{\tau} T^{\tau\tau} = 0$

0+1D, $u^\mu = 1, 0, 0, 0$, $T_{\text{id}}^{\mu\nu} = \text{diag}(\varepsilon, \rho, \rho, \rho/\tau^2)$,
the only nonzero $\pi^{\mu\nu}$ is $\tau^2 \pi^{\eta\eta} = -\frac{4}{3} \frac{\eta}{\tau}$

$$\frac{\partial \varepsilon}{\partial \tau} + \frac{\varepsilon + \rho + \tau^2 \pi^{\eta\eta}}{\tau} = 0$$

Assuming the EoS for relativistic massless gas, $\varepsilon = \alpha T^4$, $s = \frac{4}{3} \frac{\varepsilon}{T}$,
the solution is:

$$T(\tau) = \left(\frac{\tau_0}{\tau}\right)^{1/3} \left[T(\tau_0) + \frac{2\eta}{3s\tau_0} \left(1 - \left(\frac{\tau_0}{\tau}\right)^{2/3} \right) \right]$$

The same solution exists for bulk viscosity

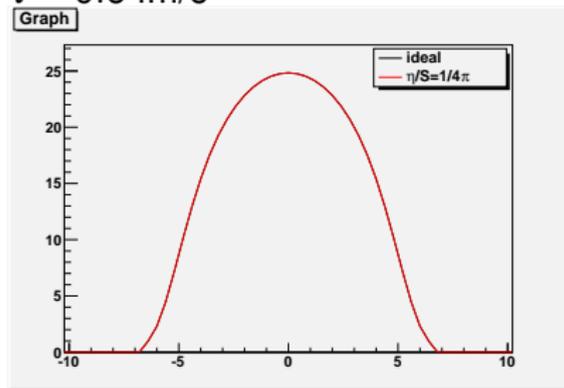

setup for test calculations³ #1

- Glauber IC for energy density
- $\tau_0 = 0.6$ fm/c, longitudinal boost-invariance
- $p = \varepsilon/3$ EoS
- Navier-Stokes values for initial $\pi^{\mu\nu}$ (nonzero due to Bjorken longitudinal flow)
- $\eta/s = 1/(4\pi)$, $\zeta/s = 0$ compared to ideal case

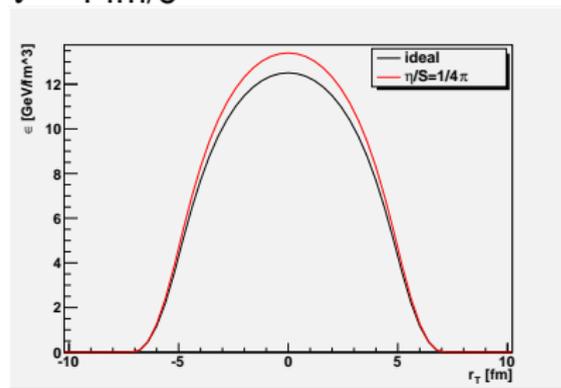

³to compare with H. Song, PhD thesis, arXiv:0908.3656

test #1: cooling rates for ideal/visc

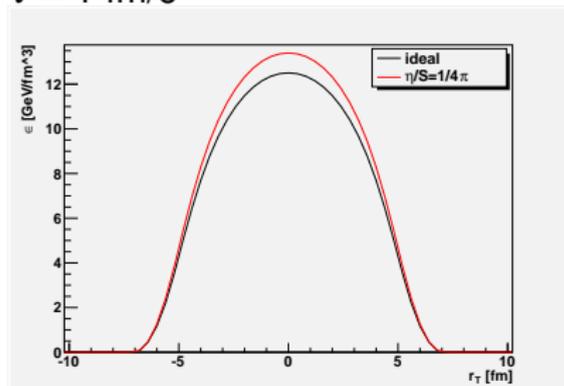

$\tau = 0.6 \text{ fm/c}$

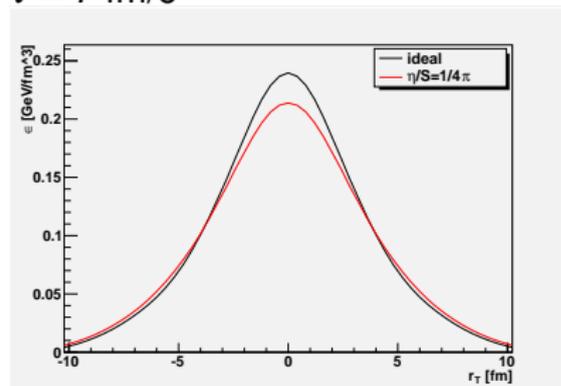

$\tau = 4 \text{ fm/c}$

$\tau = 1 \text{ fm/c}$

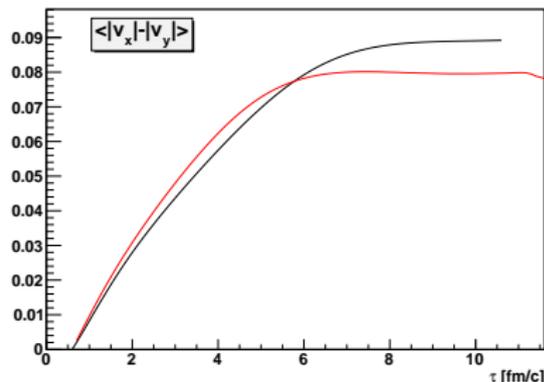

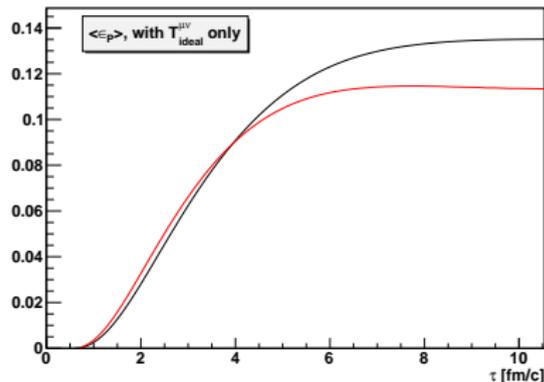

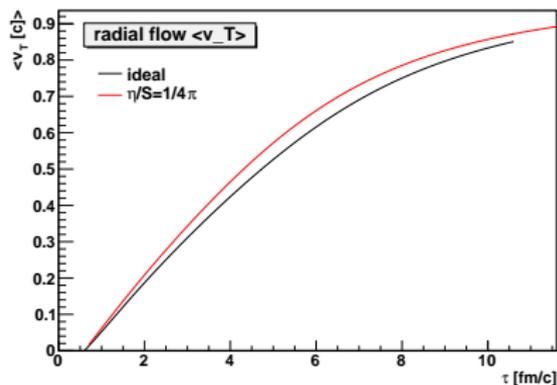

$\tau = 7 \text{ fm/c}$

test #1: additional transverse push & anizotropy suppression

Central and noncentral collisions:
Glauber IC, $b = 7$ fm
