Transport Theory Seminar, FIAS Frankfurt, November 11, 2015

DUBNA

Baryon stopping signal for a Phase Transition in Heavy-Ion Collisions

David Blaschke

University of Wroclaw, Poland & JINR Dubna, Russia

1. Introduction:

The baryon stopping signal for a 1st order phase transition

2. Robustness: The dependence on experimental cuts

Based on arxiv:1504.03992 [with Yu. Ivanov]

3. Further developments:

Particization, Detector response, UrQMD, new class EoS

High-Density Matter Seminar, BLTP JINR Dubna, June 24, 2015

Strategy towards event simulations testing PT signal

Two alternative approaches:

I) Direct approach based on transport codes:

Particle trajectories are followed;

Properties of the medium are encoded in propagators and cross sections

→ UrQMD (Aichelin et al.),

→ PHSD (Bratkovskaya, Cassing, et al.),

→ PHSD + SACA (Bratkovskaya, Aichelin, LeFevre, et al.)

II) Hybrid approach:

Joins hydrodynamic evolution of a (multi-)fluid system described by an **EoS** with

Particle transport via a procedure called “**particlization**” (Karpenko)

Particularly suitable for studying effects of a strong phase transition in model EoS

a) Sandwich: UrQMD + hydro + hadronic cascade (H. Petersen et al.)

→ PT in hydro stage only

b) **3-fluid hydro**dynamics (Ivanov) + particlization (Karpenko)

→ PT in baryon stopping regime already!

(main difference to sandwich; appropriate for energy range of NICA / CBM)

Both approaches provide the inputs for the simulation of the **detector response**
(GEANT-MPD: Rogachevsky, Voronyuk, Batyuk, Wielanek, et al.)

Hydrodynamic modelling for NICA / FAIR

More complicated for lower energies:

- baryon stopping effects,
- finite baryon chemical potential,
- EoS unknown from first principles

We want to simulate the effects of, and ultimately discriminate different EoS/PT types
The model has to be coupled to a detector response code to simulate detector events

Summary

Produced particles populate mid-rapidity
 \Rightarrow **fireball** fluid

distribution function

momentum along beam

Target-like fluid:

$$\partial_\mu J_t^\mu = 0$$

Leading particles carry bar. charge

$$\partial_\mu T_t^{\mu\nu} = -F_{tp}^\nu + F_{ft}^\nu$$

exchange/emission

Projectile-like fluid:

$$\partial_\mu J_p^\mu = 0,$$

$$\partial_\mu T_p^{\mu\nu} = -F_{pt}^\nu + F_{fp}^\nu$$

Fireball fluid:

$$J_f^\mu = 0,$$

Baryon-free fluid

$$\partial_\mu T_f^{\mu\nu} = F_{pt}^\nu + F_{tp}^\nu - F_{fp}^\nu - F_{ft}^\nu$$

Source term Exchange

The **source term** is delayed due to a formation time $\tau \sim 1 \text{ fm/c}$

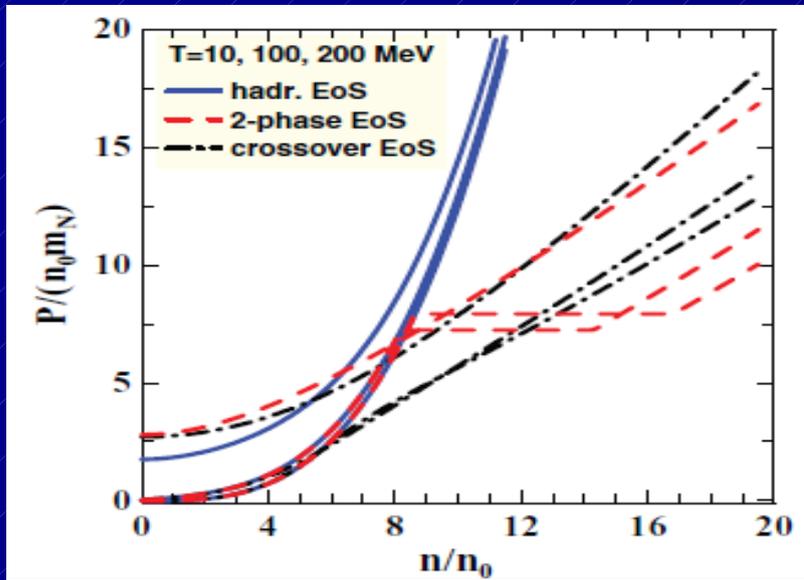

Total energy-momentum conservation:

$$\partial_\mu (T_p^{\mu\nu} + T_t^{\mu\nu} + T_f^{\mu\nu}) = 0$$

Net proton rapidity distribution – test case for a 1st order PT signal

Theory: Yu.B. Ivanov, Phys. Rev. C 87, 064904 (2013)

EoS

3-fluid hydro
Evolution ...

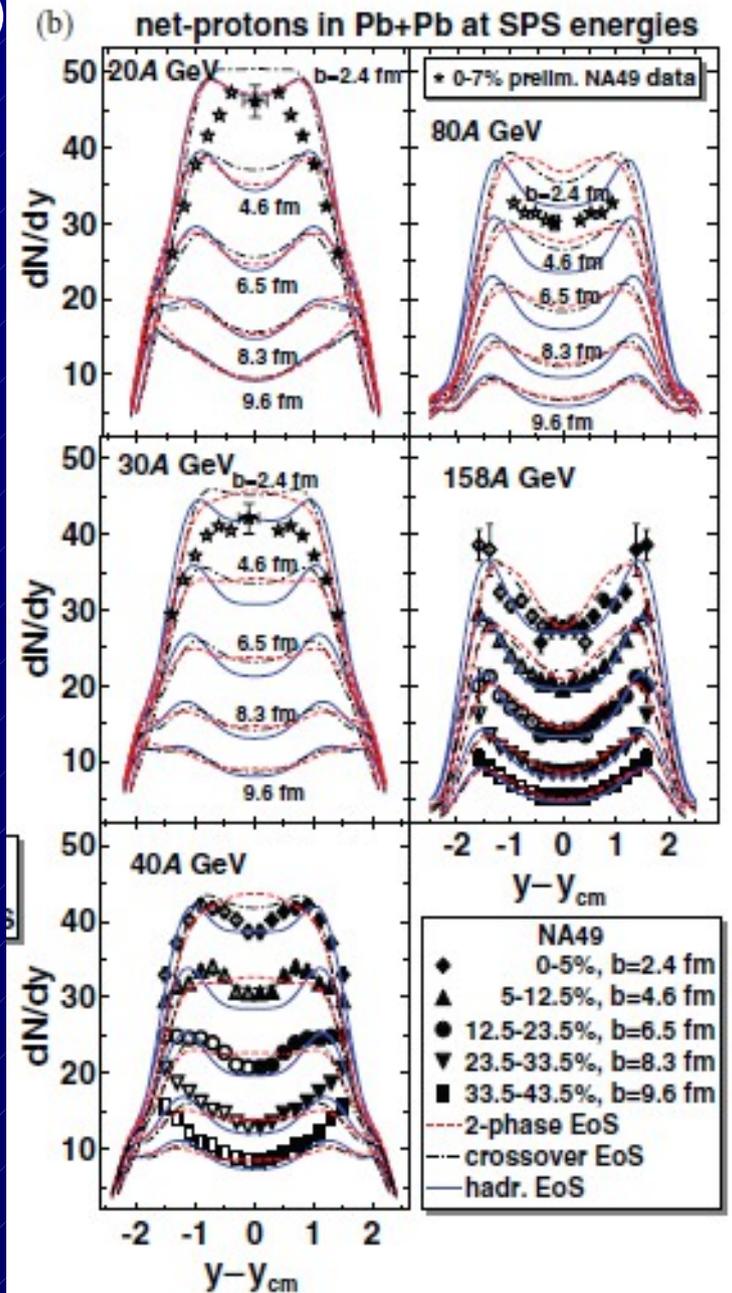

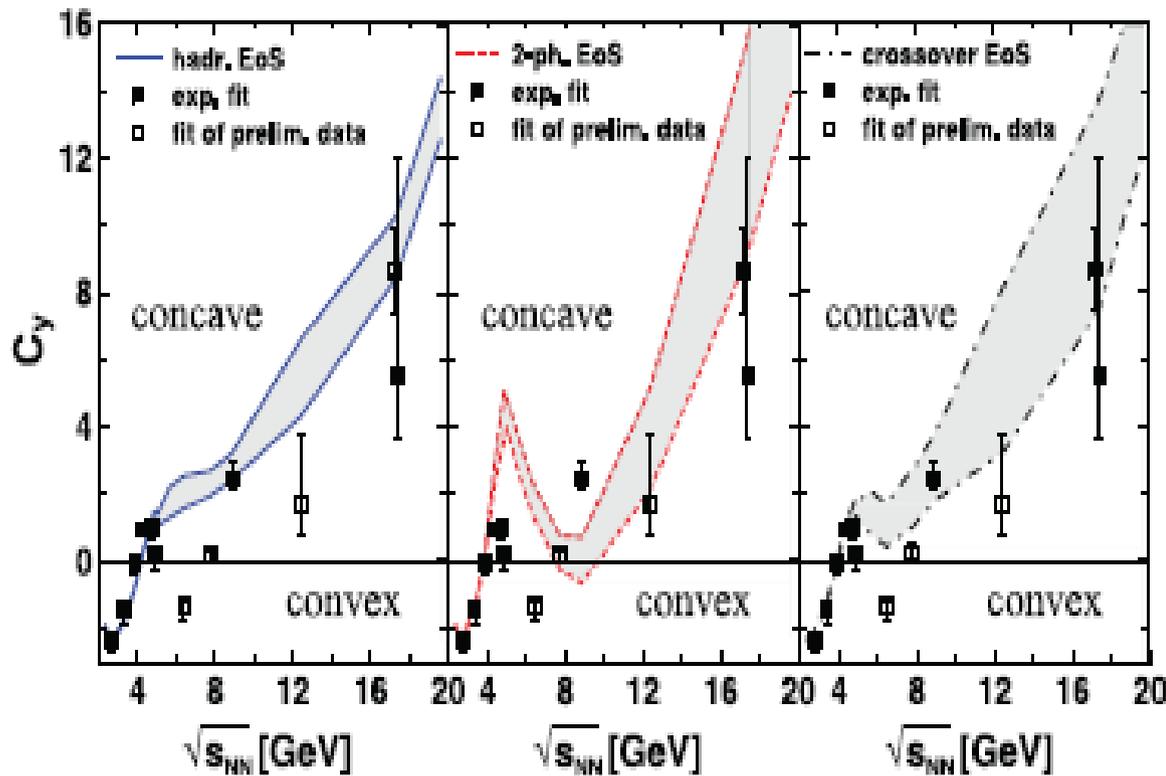

Net proton rapidity distribution – test case for a 1st order PT signal

Theory: Yu.B. Ivanov, Phys. Rev. C 87, 064904 (2013)

$$C_y = \left(y_{c.m.}^3 \frac{d^3 N}{dy^3} \right)_{y=y_{c.m.}} / \left(y_{c.m.} \frac{dN}{dy} \right)_{y=y_{c.m.}}$$

$$= (y_{c.m.}/w_s)^2 (\sinh^2 y_s - w_s \cosh y_s).$$

Net proton rapidity distribution – test case for a 1st order PT signal

Event set:

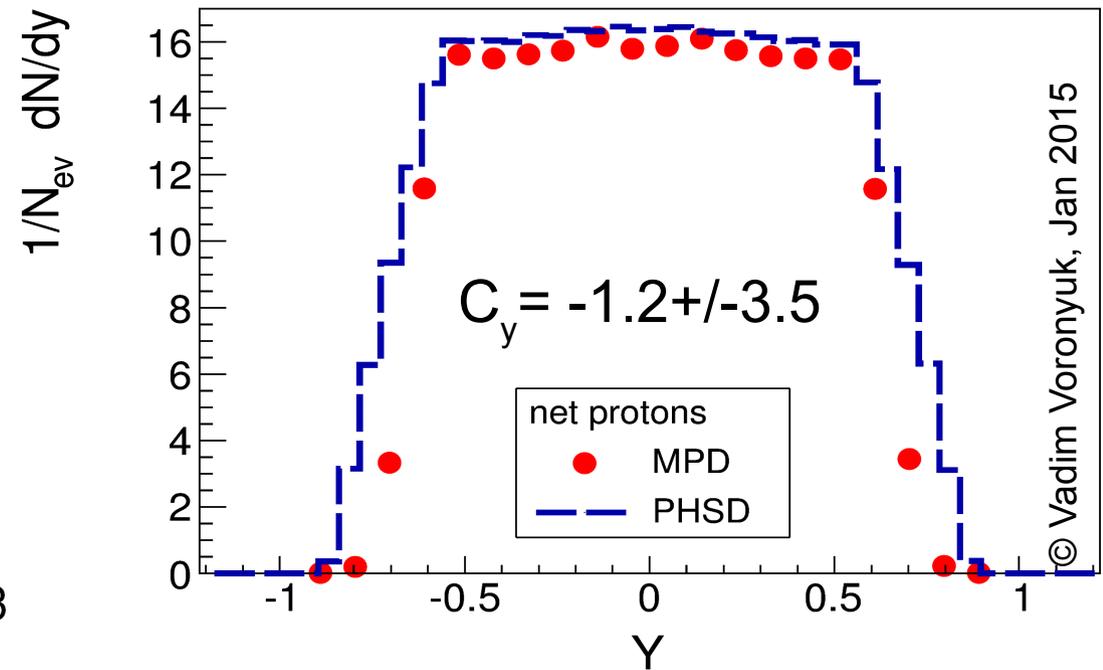

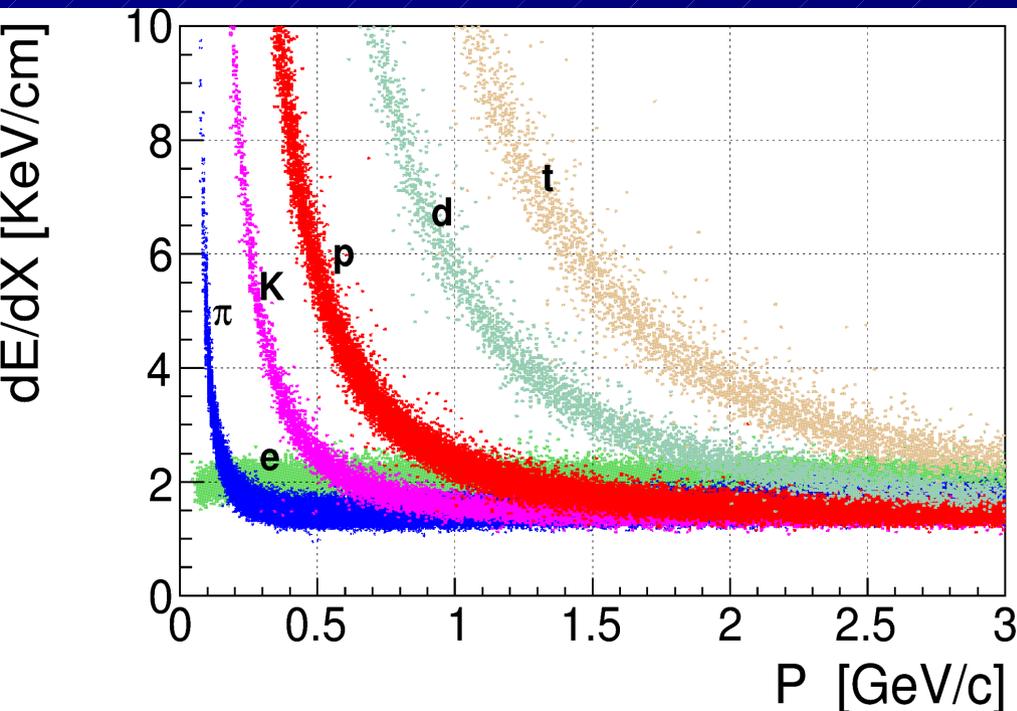

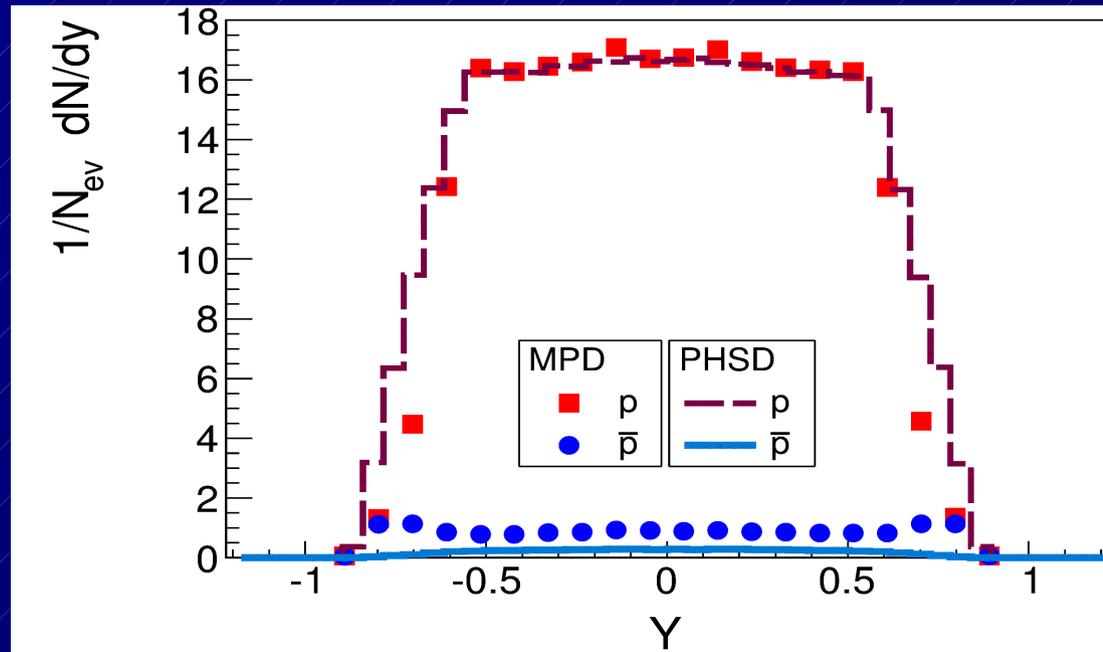

40k AuAu @ $\sqrt{s}_{NN} = 9$ GeV [0-5%]
 The most reliable region
 $|\eta| < 1.2$; $0.4 < p_t$ [GeV/c] < 0.8

Result:

PHSD input \rightarrow GEANT+MPD
 detector reproduces the rapidity distribution !
 (previous concerns not confirmed !!)

Signal:

$$C_y = \left(y_{cm}^3 \frac{d^3 N}{dy^3} \right)_{y=0} / \left(y_{cm} \frac{dN}{dy} \right)_{y=0}$$

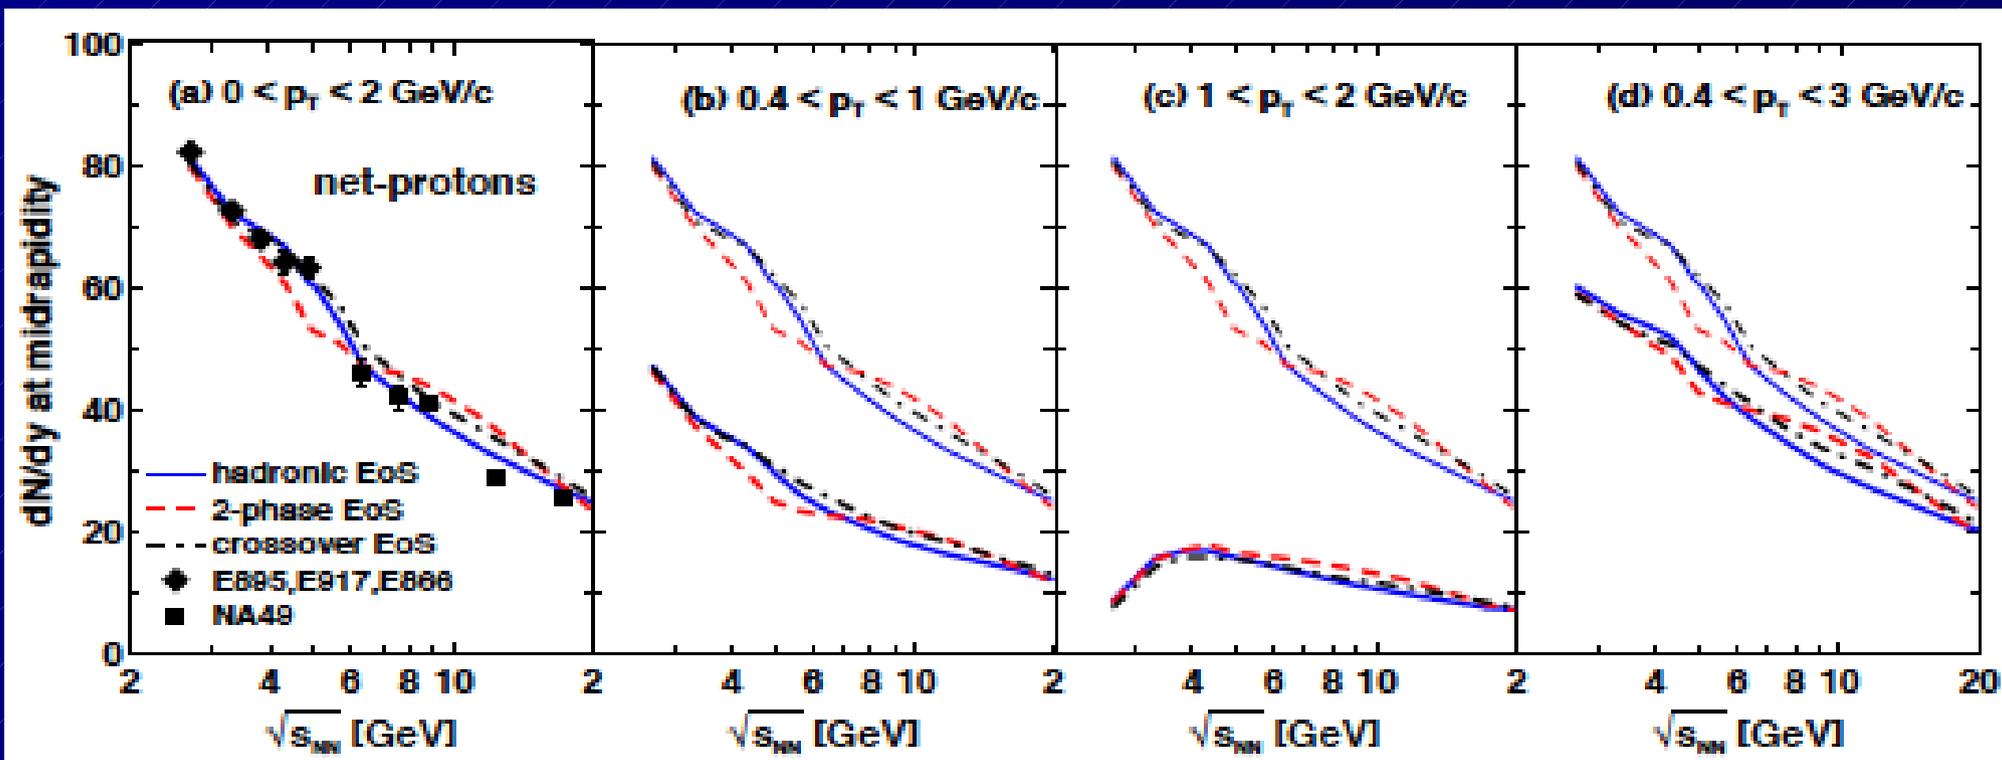

Net proton rapidity distribution – test case for a 1st order PT signal

Investigation of p_T cuts:

Yu. Ivanov & D. Blaschke, arxiv:1504.03992

$$C_y = \left(y_{\text{beam}}^3 \frac{d^3 N}{dy^3} \right)_{y=0} / \left(y_{\text{beam}} \frac{dN}{dy} \right)_{y=0} = (y_{\text{beam}}/w_s)^2 (\sinh^2 y_s - w_s \cosh y_s).$$

- i. $0 < p_T < 2 \text{ GeV}/c$ and a very unrestrictive constraint to the rapidity range $|y| < 0.7 y_{\text{beam}}$, where y_{beam} is the beam rapidity in the collider mode, which is practically equivalent to the full acceptance;
- ii. $0.4 < p_T < 1 \text{ GeV}/c$ and $|y| < 0.5$, the expected MPD acceptance [17];
- iii. $1 < p_T < 2 \text{ GeV}/c$ and $|y| < 0.5$, an acceptance range where low-momentum particles witnessing collective behaviour are largely eliminated;
- iv. $0.4 < p_T < 3 \text{ GeV}/c$ and $|y| < 0.5$, the range of the STAR acceptance [18].

Net proton rapidity distribution – test case for a 1st order PT signal

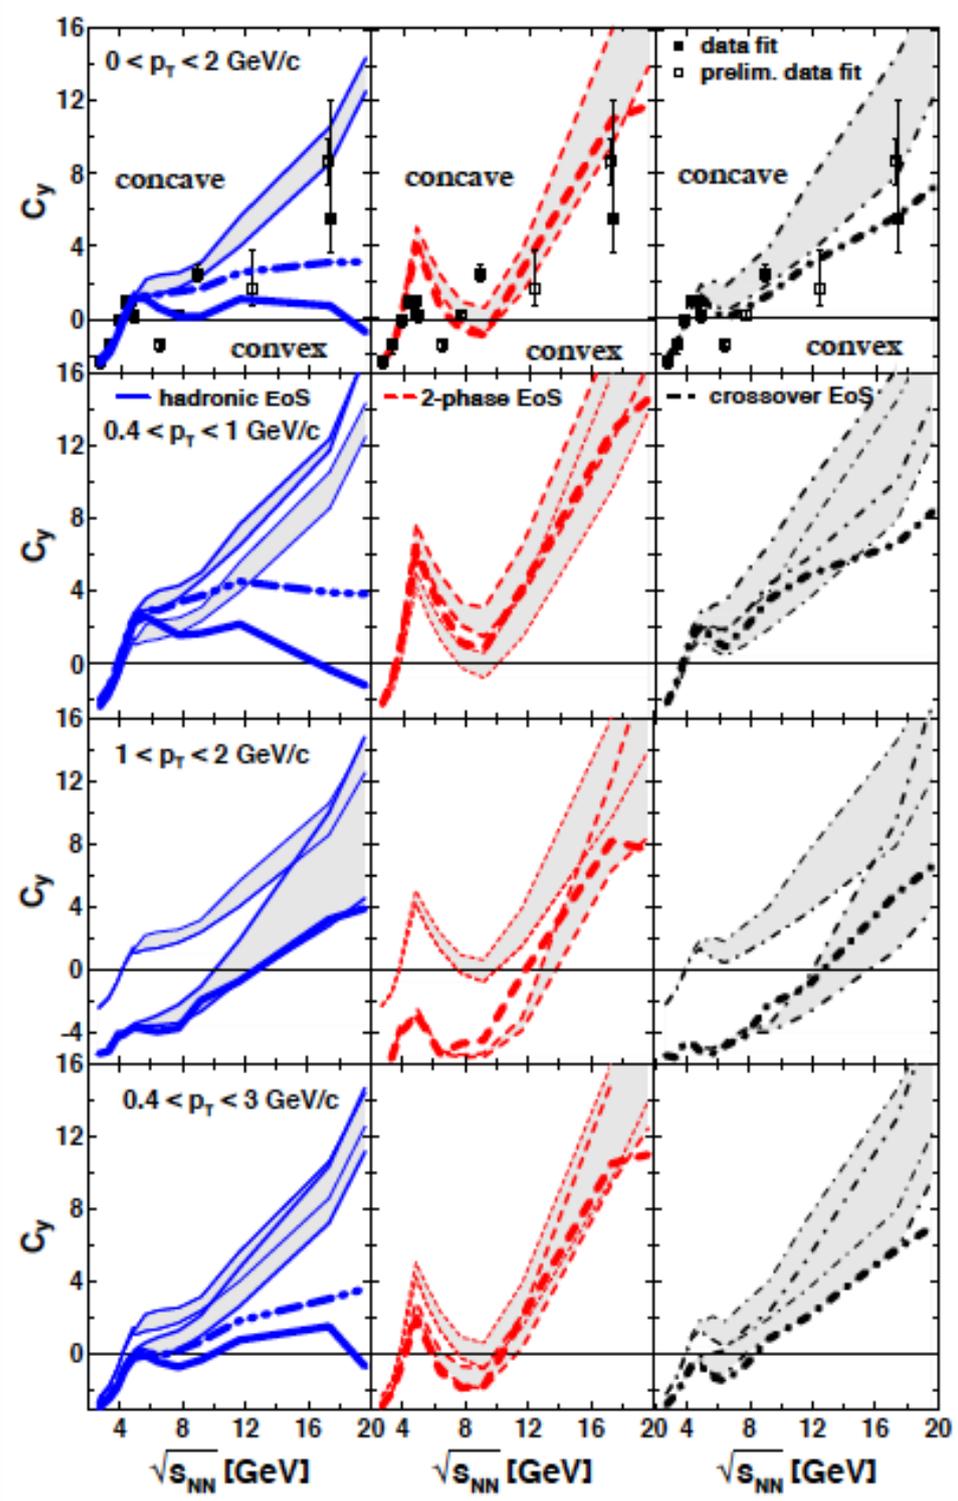

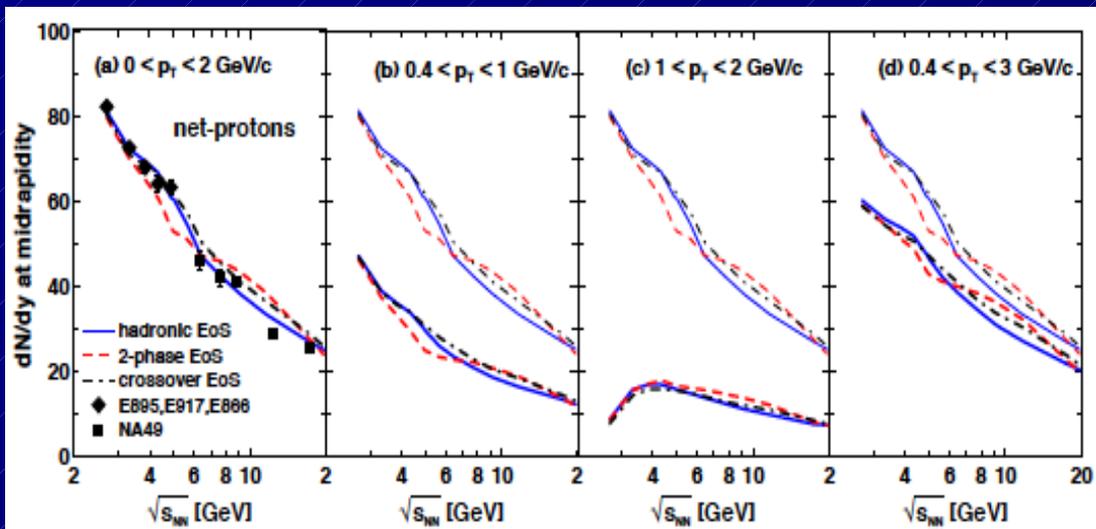

Investigation of p_T cuts:

Yu. Ivanov & D. B., PRC 92, 024916 (2015)

$$C_y = \left(y_{\text{beam}}^3 \frac{d^3 N}{dy^3} \right)_{y=0} / \left(y_{\text{beam}} \frac{dN}{dy} \right)_{y=0}$$

$$= (y_{\text{beam}}/w_s)^2 (\sinh^2 y_s - w_s \cosh y_s)$$

- “wiggle” formed in the nonequilibrium compression stage of the collision, where p_T **only in 3FH**
- robust against serious p_T cuts
- at high p_T (1 - 2 GeV/c) in convex region
- at low p_T (0.2 - 1 GeV/c) in concave region
- required accuracy in C_y determination: $\Delta C_y < 2$

Net proton rapidity distribution – test case for a 1st order PT signal

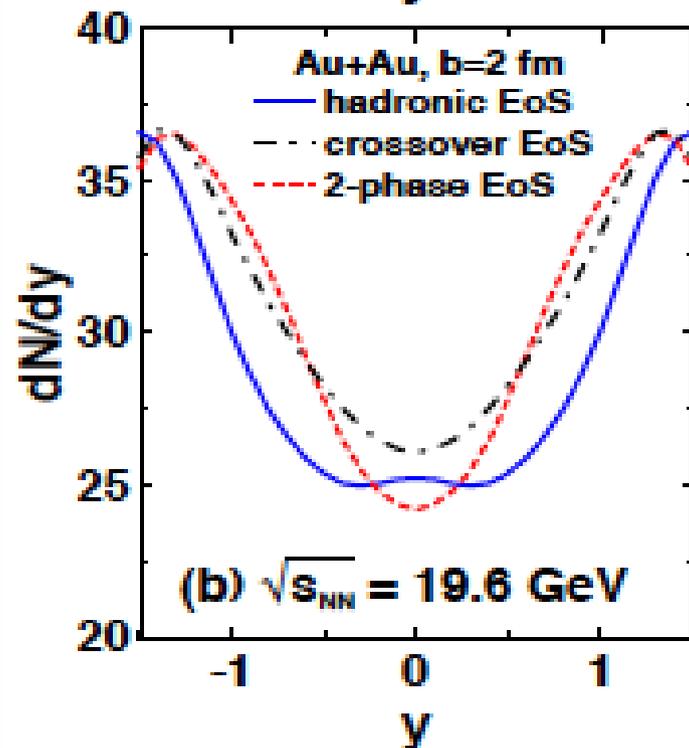

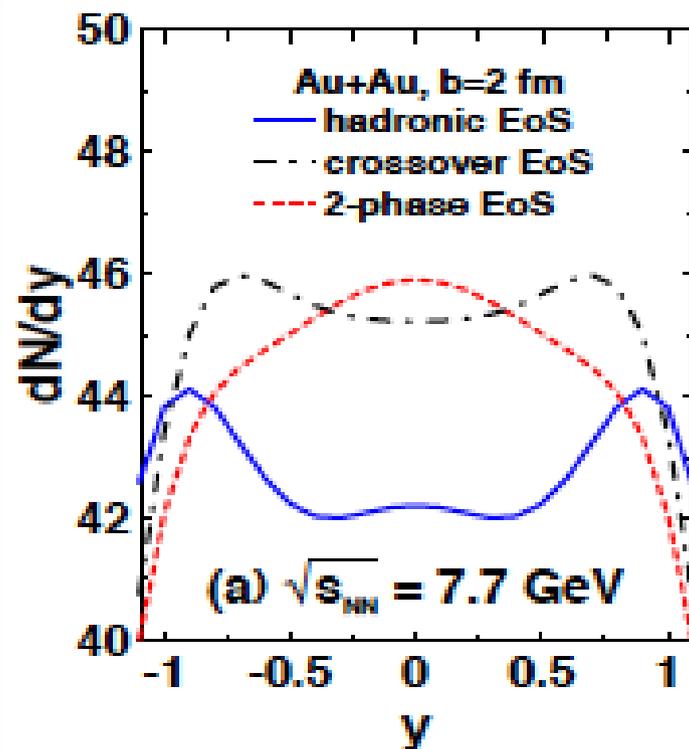

Investigation of p_T cuts:

Yu. Ivanov & D. Blaschke, arxiv:1504.03992

$$\frac{dN}{dy} = a \left(\exp \left\{ -\left(1/w_s\right) \cosh(y - y_s) \right\} + \exp \left\{ -\left(1/w_s\right) \cosh(y + y_s) \right\} \right),$$

$$C_y = \left(y_{\text{beam}}^3 \frac{d^3 N}{dy^3} \right)_{y=0} / \left(y_{\text{beam}} \frac{dN}{dy} \right)_{y=0} = (y_{\text{beam}}/w_s)^2 (\sinh^2 y_s - w_s \cosh y_s).$$

- “wiggle” formed in the nonequilibrium compression stage of the collision, where p_T **only in 3FH**
- robust against serious p_T cuts
- at high p_T (1 - 2 GeV/c) in convex region
- at low p_T (0.2 - 1 GeV/c) in concave region
- required accuracy in C_y determination: $\Delta C_y < 2$

3+1D viscous hydro-cascade model (Yu. Karpenko, FIAS)

3+1D viscous hydro+cascade model was applied for A+A collisions at RHIC Beam Energy Scan energies ($\sqrt{s} = 7.7 - 39$ GeV), and for SPS energy points

Cascade-hydro-cascade approach:

Initial state: UrQMD cascade

S.A. Bass et al., Prog. Part. Nucl. Phys. 41 255-369, 1998

Hydrodynamic phase: numerical 3+1D hydro solution via original relativistic viscous hydro code

Iu. Karpenko, P. Huovinen, M. Bleicher, arXiv:1312.4160

Hydro starts at $\tau = \sqrt{t^2 - z^2} = \tau_0$ (red curve):

$$\tau_0 = \frac{2R}{\gamma v_z}$$

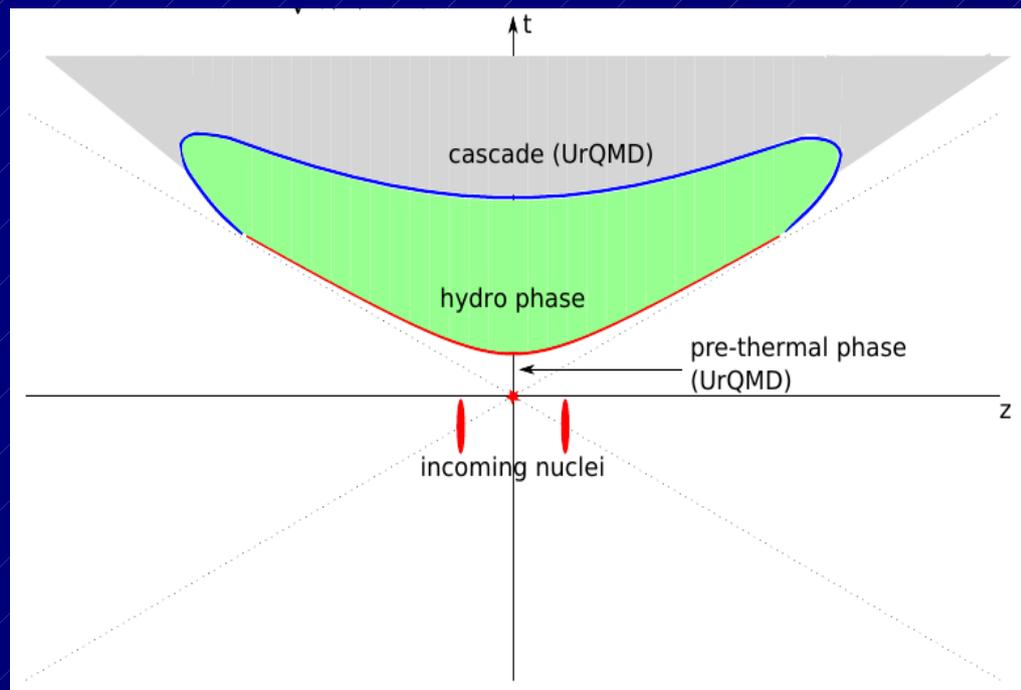

$\{T^{0\mu}, N_b^0, N_q^0\}$ of fluid = averaged $\{T^{0\mu}, N_b^0, N_q^0\}$ of particles

Fluid \rightarrow particle transition

$\varepsilon = \varepsilon_{SW} = 0.5 \text{ GeV/fm}^3$ (blue curve):

$\{T^{0\mu}, N_b^0, N_q^0\}$ of hadron-resonance gas = $\{T^{0\mu}, N_b^0, N_q^0\}$ of fluid

Hadronic cascade: UrQMD

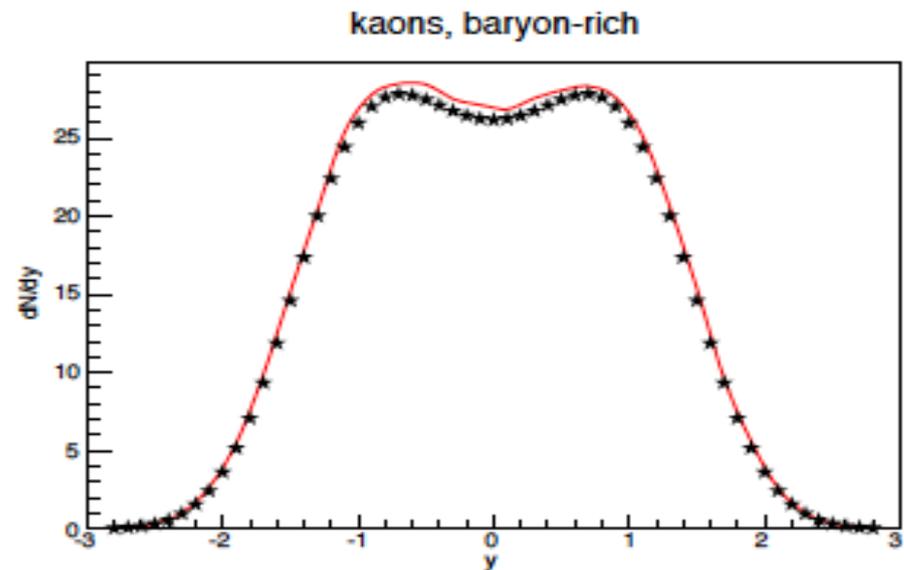

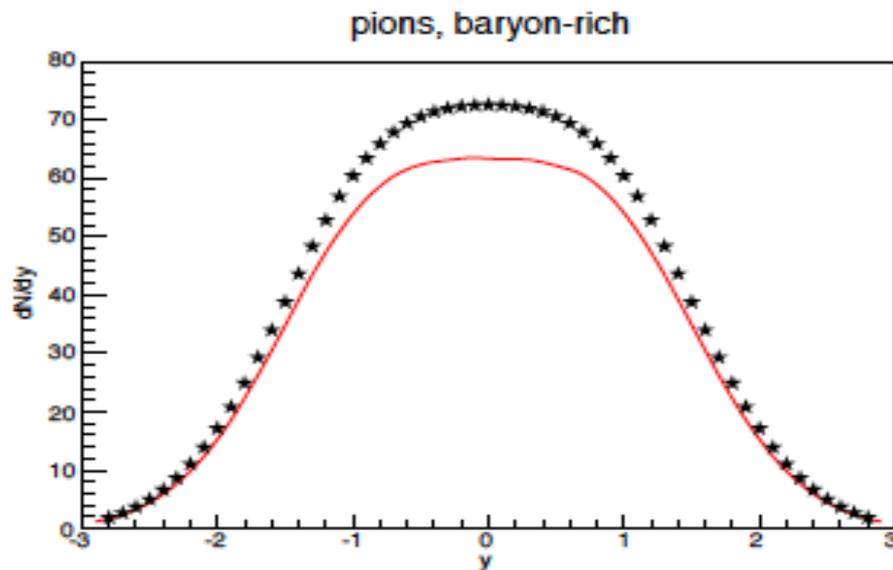

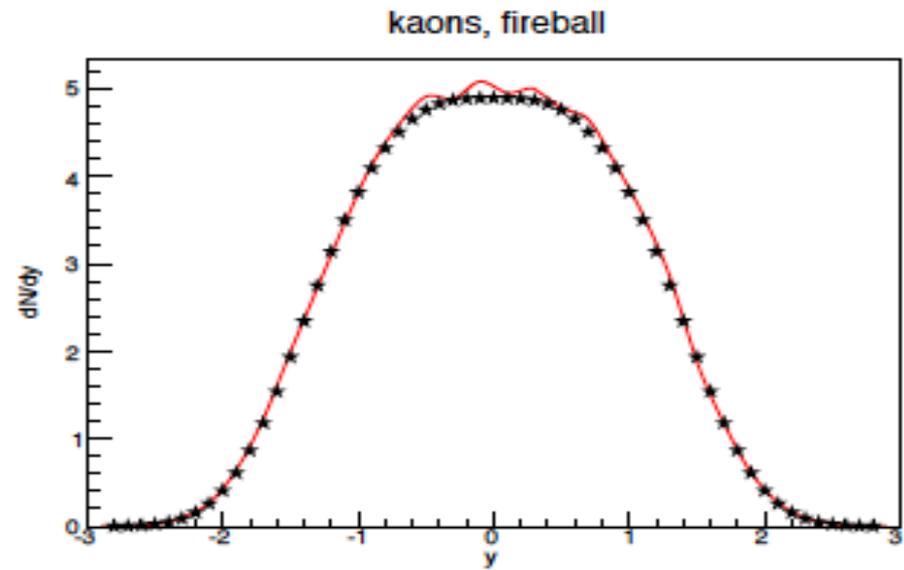

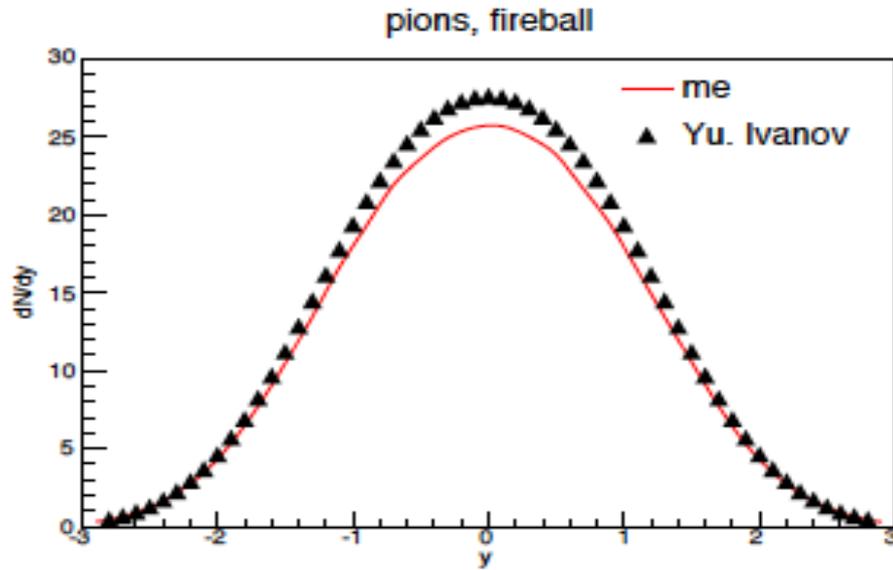

Equations of state for hydrodynamic phase

- Chiral model
 - ▶ coupled to Polyakov loop to include the deconfinement phase transition
 - ▶ good agreement with lattice QCD data at $\mu_B = 0$, also applicable at finite baryon densities
 - ▶ (current version) has **crossover type PT** between hadron and quark-gluon phase at all μ_B
- Hadron resonance gas + Bag Model (a.k.a. EoS Q)
 - ▶ hadron resonance gas made of u, d quarks including repulsive meanfield
 - ▶ the phases matched via Maxwell construction, resulting in **1st order PT**

- New 2-phase EoS (David Blaschke et al.)**

**A new class of 2-phase EoS:
Motivation from Astrophysics**

Modern 2-phase EoS in Astrophysics of Compact Stars

1. Pauli blocking effect → Excluded volume

Well known from modeling dissociation of clusters in the supernova EoS:

- excluded volume: Lattimer-Swesty (1991), Shen-Toki-Oyematsu-Sumiyoshi (1996), ...
- Pauli blocking: Roepke-Grigo-Sumiyoshi-Shen (2003), Typel et al. PRC 81 (2010)
- excl. Vol. vs. Pauli blocking: Hempel, Schaffner-Bielich, Typel, Roepke PRC 84 (2011)

Here: nucleons as quark clusters with finite size --> excluded volume effect !

Available volume fraction: $\Phi = V_{\text{av}}/V = 1 - v \sum_{i=n,p} n_i$, $v = \frac{1}{2} \frac{4\pi}{3} (2r_{\text{nuc}})^3 = 4V_{\text{nuc}}$

Equations of state for T=0 nuclear matter: $p_{\text{tot}}(\mu_n, \mu_p) = \frac{1}{\Phi} \sum_{i=n,p} p_i + p_{\text{mes}}$,

$$p_i = \frac{1}{4} (E_i n_i - m_i^* n_i^{(s)}),$$

$$\varepsilon_{\text{tot}}(\mu_n, \mu_p) = -p_{\text{tot}} + \sum_{i=n,p} \mu_i n_i,$$

$$n_i = \frac{\Phi}{3\pi^3} k_i^3,$$

$$n_i^{(s)} = \frac{\Phi m_i^*}{2\pi^2} \left[E_i k_i - (m_i^*)^2 \ln \frac{k_i + E_i}{m_i^*} \right],$$

Effective mass: $m_i^* = m_i - S_i$.

Scalar meanfield: $S_i \sim n_i^{(s)}$

$$E_i = \sqrt{k_i^2 + (m_i^*)^2} = \mu_i - V_i - \frac{v}{\Phi} \sum_{j=p,n} p_j,$$

Vector meanfield: $V_i \sim n_i$

Modern 2-phase EoS in Astrophysics of Compact Stars

2. Stiff quark matter at high densities

S. Benic, Eur. Phys. J. A 50, 111 (2014)

$$\mathcal{L} = \bar{q}(i\partial - m)q + \mu_q \bar{q}\gamma^0 q + \mathcal{L}_4 + \mathcal{L}_8, \quad \mathcal{L}_4 = \frac{g_{20}}{\Lambda^2} [(\bar{q}q)^2 + (\bar{q}i\gamma_5\tau q)^2] - \frac{g_{02}}{\Lambda^2} (\bar{q}\gamma_\mu q)^2,$$
$$\mathcal{L}_8 = \frac{g_{40}}{\Lambda^8} [(\bar{q}q)^2 + (\bar{q}i\gamma_5\tau q)^2]^2 - \frac{g_{04}}{\Lambda^8} (\bar{q}\gamma_\mu q)^4 - \frac{g_{22}}{\Lambda^8} (\bar{q}\gamma_\mu q)^2 [(\bar{q}q)^2 + (\bar{q}i\gamma_5\tau q)^2]$$

Meanfield approximation: $\mathcal{L}_{\text{MF}} = \bar{q}(i\partial - M)q + \tilde{\mu}_q \bar{q}\gamma^0 q - U,$

$$M = m + 2\frac{g_{20}}{\Lambda^2} \langle \bar{q}q \rangle + 4\frac{g_{40}}{\Lambda^8} \langle \bar{q}q \rangle^3 - 2\frac{g_{22}}{\Lambda^8} \langle \bar{q}q \rangle \langle q^\dagger q \rangle^2,$$

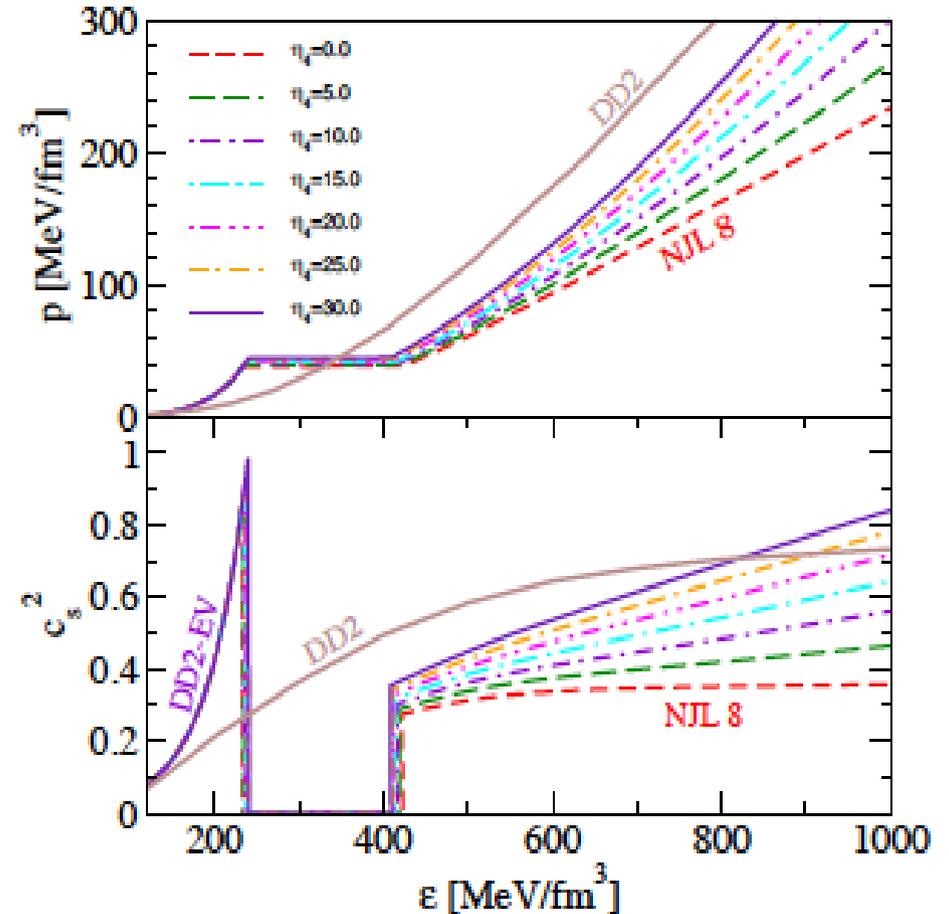

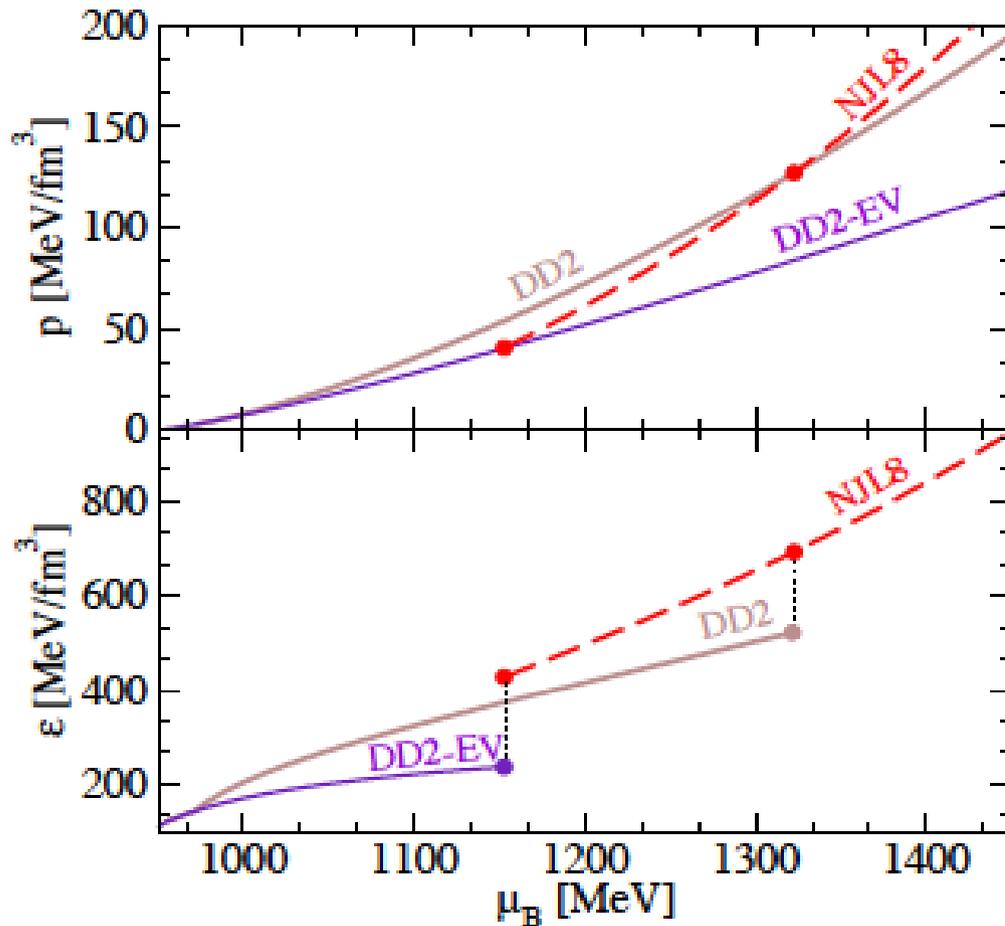

$$\tilde{\mu}_q = \mu_q - 2\frac{g_{02}}{\Lambda^2} \langle q^\dagger q \rangle - 4\frac{g_{04}}{\Lambda^8} \langle q^\dagger q \rangle^3 - 2\frac{g_{22}}{\Lambda^8} \langle \bar{q}q \rangle^2 \langle q^\dagger q \rangle,$$

$$U = \frac{g_{20}}{\Lambda^2} \langle \bar{q}q \rangle^2 + 3\frac{g_{40}}{\Lambda^8} \langle \bar{q}q \rangle^4 - 3\frac{g_{22}}{\Lambda^8} \langle \bar{q}q \rangle^2 \langle q^\dagger q \rangle^2 - \frac{g_{02}}{\Lambda^2} \langle q^\dagger q \rangle^2 - 3\frac{g_{04}}{\Lambda^8} \langle q^\dagger q \rangle^4.$$

Thermodynamic Potential:

$$\Omega = U - 2N_f N_c \int \frac{d^3 p}{(2\pi)^3} \left\{ E + T \log[1 + e^{-\beta(E - \tilde{\mu}_q)}] + T \log[1 + e^{-\beta(E + \tilde{\mu}_q)}] \right\} + \Omega_0$$

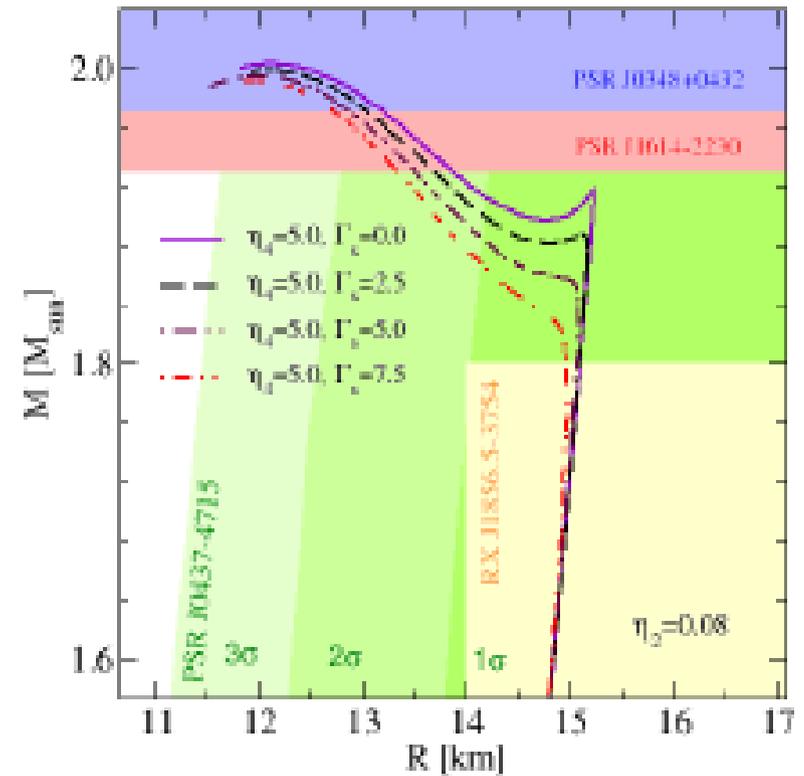

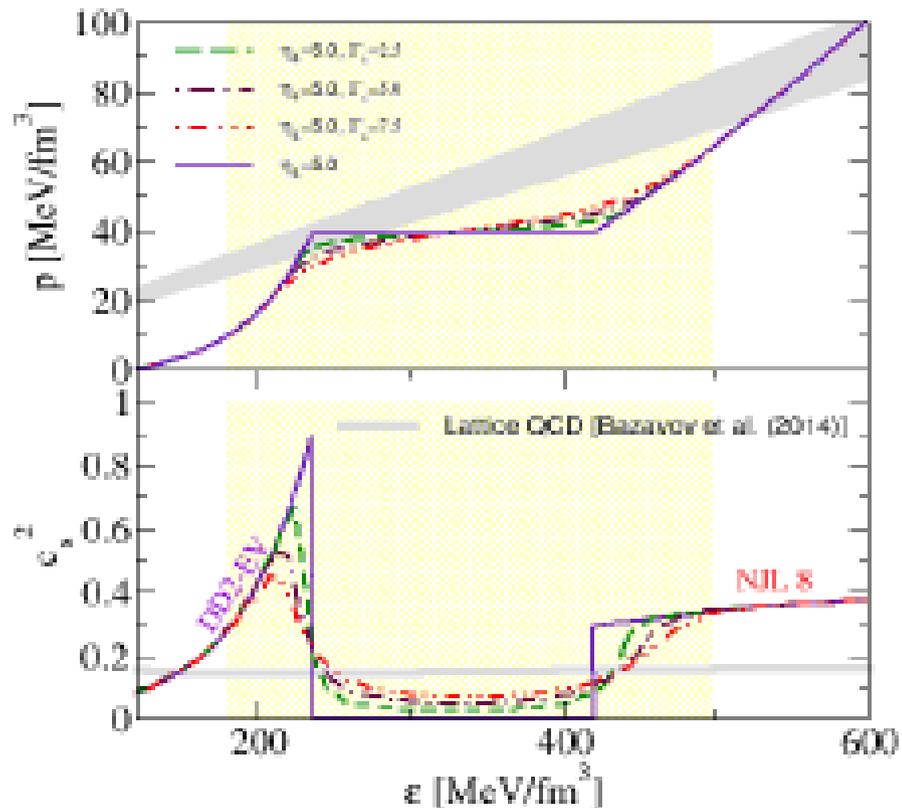

Modern 2-phase EoS in Astrophysics of Compact Stars

Here: Stiffening of dense hadronic matter by excluded volume in density-dependent RMF
 Stiffening of dense quark matter by higher order quark vector current interactions (η_4)

Modern 2-phase EoS in Astrophysics of Compact Stars

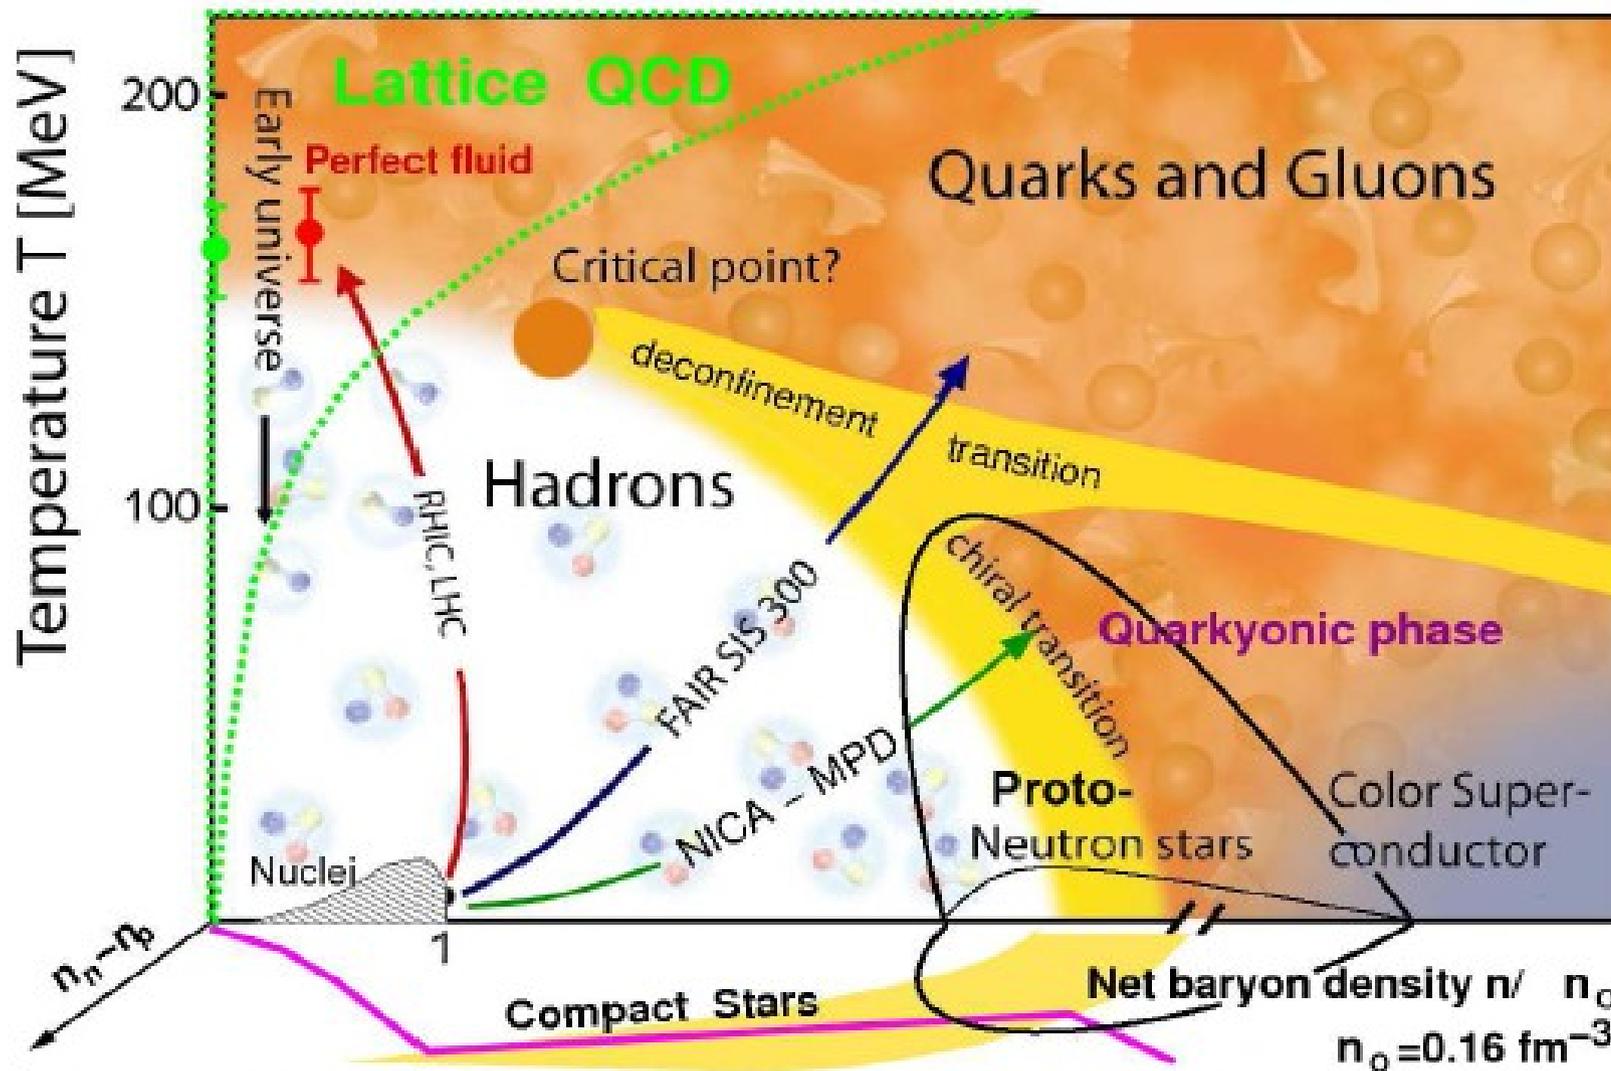

Estimate effects of structures in the phase transition region (“pasta”)

High-mass Twins relatively robust against “smoothing” the Maxwell transition construction

NICA White Paper, <http://theor.jinr.ru/twiki-cgi/view/NICA/WebHome>

Crossover at finite T (Lattice QCD) + First order at zero T (Astrophysics) = Critical endpoint exists!

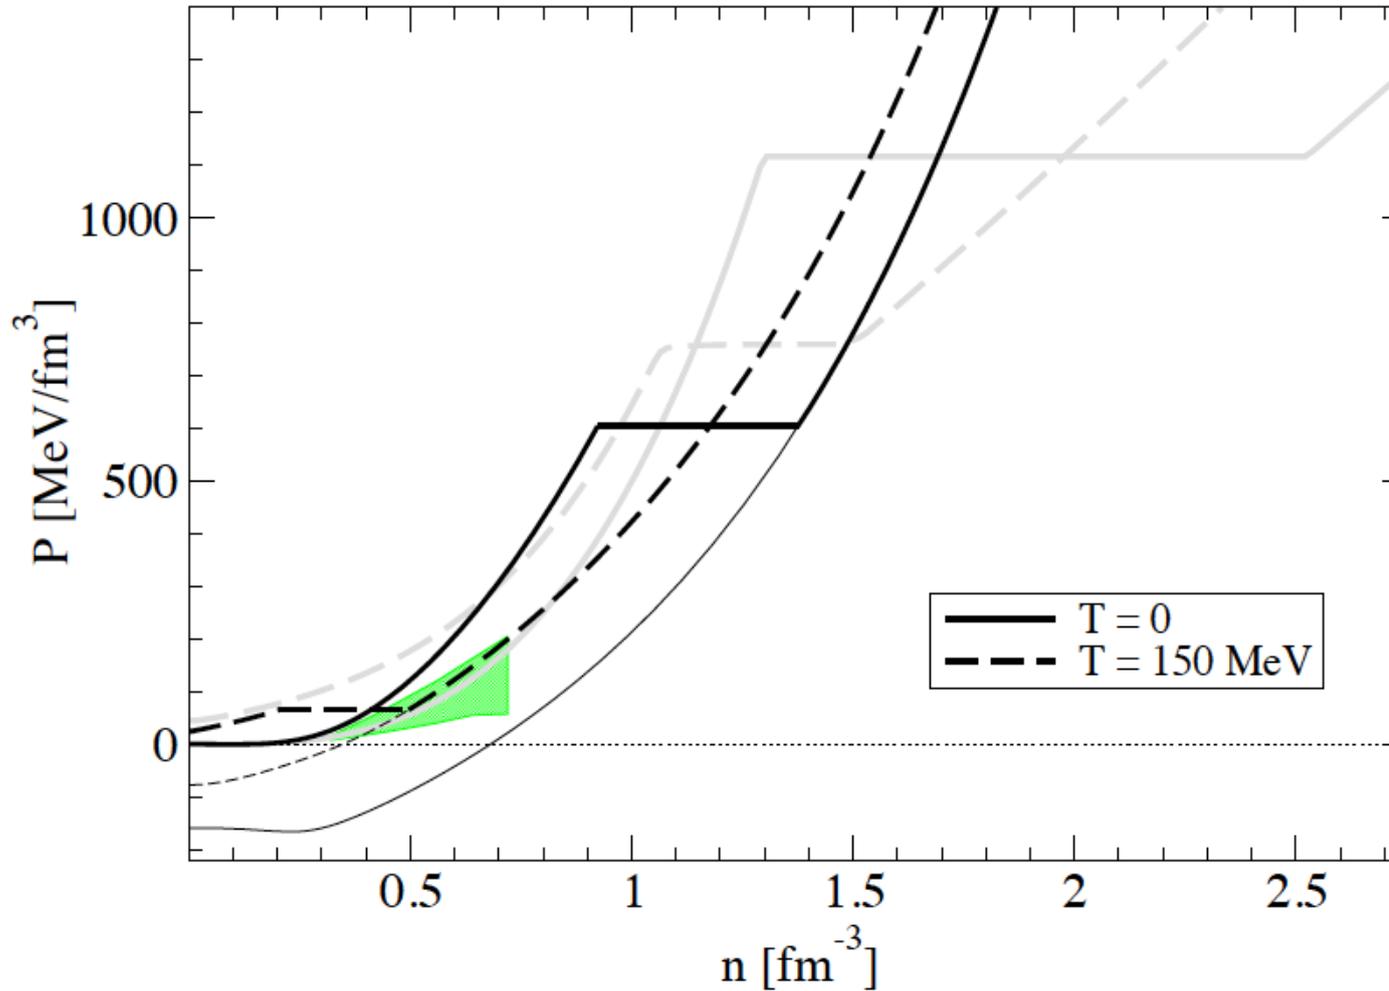

Comparison 2-phase EoS

N.-U. Bastian, D. Blaschke (S. Benic, S. Typel),
In progress (2015)

A. Khvorostukhin et al. EPJC 48 (2006) 531
Yu. Ivanov, D. Blaschke, arxiv:1504.03992

Comparison 2-phase EoS

Grey: Ivanov (2010)

Black: DD2 vs. HNJLb

$B=160 \text{ MeV}/\text{fm}^3$

Summary / Outlook:

- Baryon stopping signal (“wiggle”) remains a robust signal for 1st order PT also under severe cuts in transverse momentum !
- Discrimination between hadronic phase and crossover transition ambiguous
- Position of the “wiggle” in the beam energy scan is EoS dependent – new EoS ?!
- Particlization of 3-Fluid Hydrodynamics model works !
- UrQMD “afterburner” works too !

- Detector simulation in progress
- Systematic study of modern 2-phase EoS (Bayesian analysis) in progress

Critical Point and Onset of Deconfinement

CPOD 2016

University of Wrocław, Poland

May 30th – June 3rd, 2016
