August 28, 2018

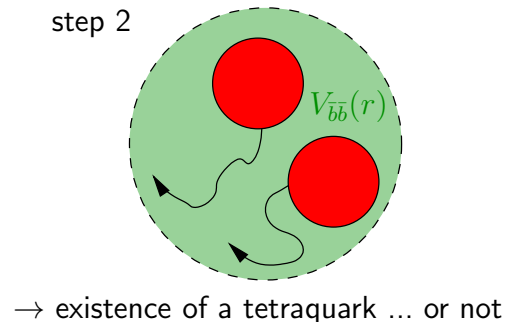

Basic idea to study $bbqq$ tetraquarks (1)

- Study heavy tetraquarks $\bar{b}\bar{b}qq$ or $\bar{b}b\bar{q}q$ in two steps.
 - (1) **Compute potentials of two static quarks ($\bar{b}\bar{b}$ or $\bar{b}b$) in the presence of two lighter quarks (qq or $\bar{q}q$, $q \in \{u, d, s, c\}$) using lattice QCD.**
→ This talk.
 - (2) **Explore, whether these potentials are sufficiently attractive to host bound states or resonances (→ tetraquarks) by using techniques from quantum mechanics and scattering theory.**
→ Next talk by Pedro Bicudo.
- ((1) + (2) → Born-Oppenheimer approximation).

step 1

step 2

Basic idea to study $bbqq$ tetraquarks (2)

- Both talks summarize

Why are such studies important? (1)

- **Meson**: system of quarks and gluons with integer total angular momentum $J = 0, 1, 2, \dots$
- Most mesons seem to be **quark-antiquark pairs** $\bar{q}q$, e.g. $\pi \equiv \bar{u}d$, $D \equiv \bar{c}d$, $\eta_s \equiv \bar{c}c$ (quark-antiquark model calculations reproduce the majority of experimental results).
- Certain mesons are poorly understood (significant discrepancies between experimental results and quark model calculations), could have a more complicated structure, e.g.
 - **2 quarks and 2 antiquarks (tetraquark)**,
 - **a quark-antiquark pair and gluons (hybrid meson)**,
 - **only gluons (glueball)**.

Why are such studies important? (2)

- Indications for tetraquark structures:

- Electrically charged mesons $Z_b(10610)^+$ and $Z_b(10650)^+$:

- * Mass suggests a $b\bar{b}$ pair ...

- * ... but $b\bar{b}$ is electrically neutral ...?

- * **Easy to understand, when assuming a tetraquark structure:**

$Z_b(\dots)^+ \equiv b\bar{b}u\bar{d}$ ($u \rightarrow +2/3 e$, $\bar{d} \rightarrow -1/3 e$).

- Electrically charged Z_c states:

- * Similar to Z_b .

- Mass ordering of light scalar mesons:

- * E.g. $m_{\kappa} > m_{a_0(980)}$...?

Outline

- $\bar{b}bqq$ / BB potentials.
- Lattice setup.
- $\bar{b}bqq$ tetraquarks.
- Inclusion of heavy spin effects.
- $\bar{b}b\bar{q}q$ / $\bar{B}B$ potentials

$\bar{b}\bar{b}qq$ / BB potentials (1)

- From now on $\bar{b}\bar{b}qq$ ($\bar{b}\bar{b}q\bar{q}$ technically more difficult, will be discussed at the end of this talk).
 - Spins of static antiquarks $\bar{b}\bar{b}$ are irrelevant (they do not appear in the Hamiltonian).
 - At large $\bar{b}\bar{b}$ separation r , the four quarks will form two static-light mesons $\bar{b}q$ and $\bar{b}q$.
 - Consider only pseudoscalar/vector mesons ($j^P = (1/2)^-$, PDG: B, B^*) and scalar/pseudovector mesons ($j^P = (1/2)^+$, PDG: B_0^*, B_1^*), which are among the lightest static-light mesons (j : spin of the light degrees of freedom).
 - Compute and study the dependence of $\bar{b}\bar{b}$ potentials in the presence of qq on
 - the “light” quark flavors $q \in \{u, d, s, c\}$ (isospin, flavor),
 - the “light” quark spin (the static quark spin is irrelevant),
 - the type of the meson B, B^* and/or B_0^*, B_1^* (parity).
- Many different channels: attractive versus repulsive, different asymptotic values ...

$\bar{b}\bar{b}qq / BB$ potentials (2)

- Rotational symmetry broken by static quarks $\bar{b}\bar{b}$.
- Remaining symmetries and quantum numbers:
 - Rotations around the separation axis (e.g. z axis), quantum number j_z .
 - P .
 - P_x (reflection along an axis perpendicular to the separation axis, e.g. x axis).
- To extract the potential(s) of a given sector ($I, I_z, |j_z|, P, P_x$), compute the temporal correlation function of the trial state

$$(C\Gamma)_{AB} (C\tilde{\Gamma})_{CD} \left(\bar{Q}_C(-\mathbf{r}/2) q_A^{(1)}(-\mathbf{r}/2) \right) \left(\bar{Q}_D(+\mathbf{r}/2) q_B^{(2)}(+\mathbf{r}/2) \right) |\Omega\rangle.$$

- $q^{(1)}q^{(2)} \in \{ud - du, uu, dd, ud + du, ss, cc\}$ (isospin I, I_z , flavor).
- Γ is an arbitrary combination of γ matrices (spin $|j_z|$, parity P, P_x).
- $\tilde{\Gamma} \in \{(1 - \gamma_0)\gamma_5, (1 - \gamma_0)\gamma_j\}$ (irrelevant).

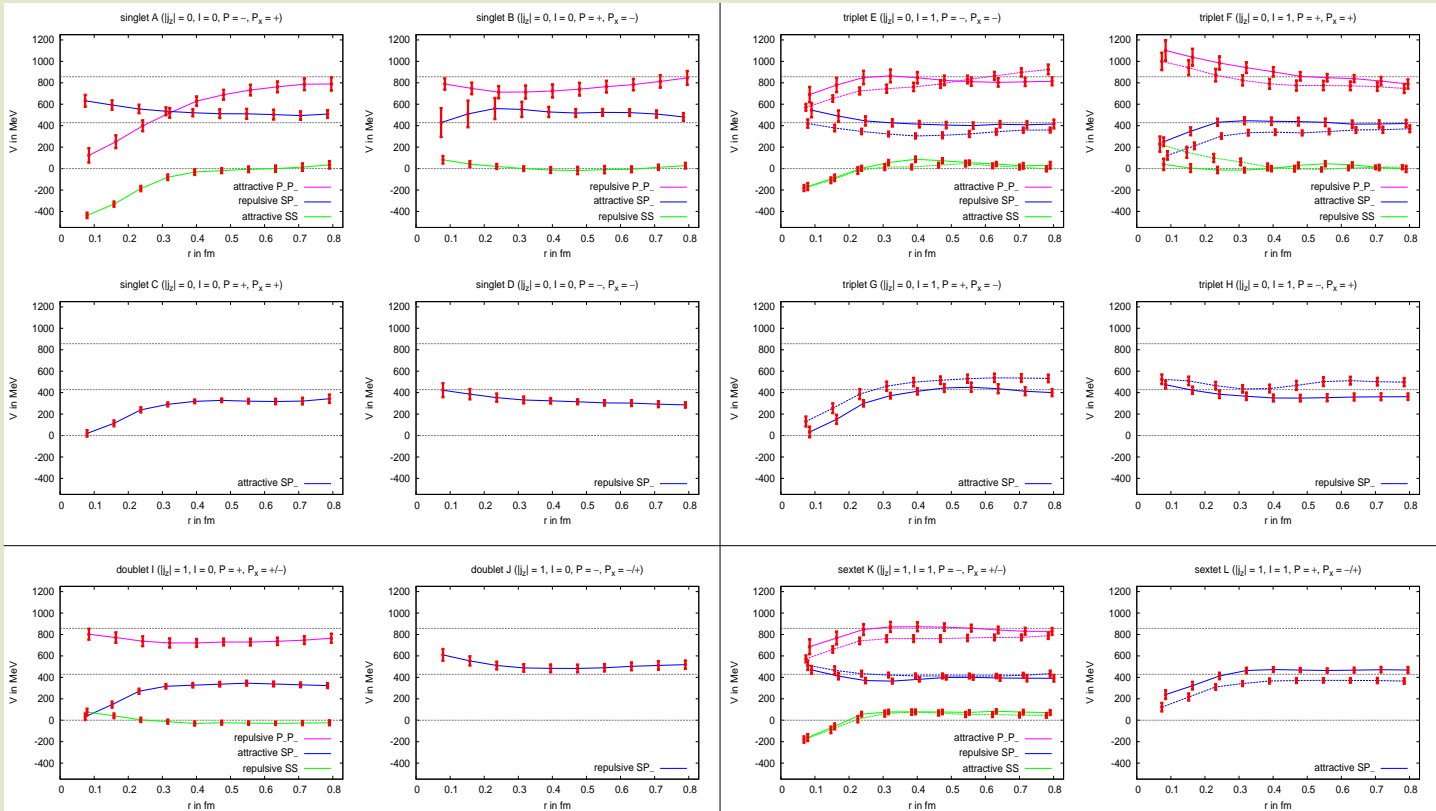

Lattice setup

- ETMC gauge link ensembles:
 - $N_f = 2$ dynamical quark flavors.
 - Lattice spacing $a \approx 0.079$ fm.
 - $24^3 \times 48$, i.e. spatial lattice extent ≈ 1.9 fm.
 - Three different pion masses $m_\pi \approx 340$ MeV, $m_\pi \approx 480$ MeV, $m_\pi \approx 650$ MeV.

[R. Baron *et al.* [ETM Collaboration], JHEP 1008, 097 (2010) [arXiv:0911.5061 [hep-lat]]

$\bar{b}\bar{b}qq$ / BB potentials (3)

- $I = 0$ (left) and $I = 1$ (right); $|j_z| = 0$ (top) and $|j_z| = 1$ (bottom).

$\bar{b}\bar{b}qq$ / BB potentials (4)

Why are there three different asymptotic values?

- Differences ≈ 400 MeV, approximately the mass difference of $B_{0,1}^*$ ($P = +$) and $B^{(*)}$ ($P = -$).
- Suggests that the three different asymptotic values correspond to $B^{(*)}B^{(*)}$ potentials, to $B^{(*)}B_{0,1}^*$ potentials and $B_{0,1}^*B_{0,1}^*$ potentials.
- Can be checked and confirmed, by rewriting the $\bar{b}\bar{b}qq$ creation operators in terms of meson-meson creation operators (Fierz transformation).
- Example: uu , $\Gamma = \gamma_3$ (attractive, lowest asymptotic value),

$$\begin{aligned} & (C\gamma_3)_{AB} \left(\bar{Q}_C(-\mathbf{r}/2)q_A^{(u)}(-\mathbf{r}/2) \right) \left(\bar{Q}_D(+\mathbf{r}/2)q_B^{(u)}(+\mathbf{r}/2) \right) \propto \\ & \propto (B^{(*)})_{\uparrow}(B^{(*)})_{\downarrow} + (B^{(*)})_{\downarrow}(B^{(*)})_{\uparrow} - (B_{0,1}^*)_{\uparrow}(B_{0,1}^*)_{\downarrow} - (B_{0,1}^*)_{\downarrow}(B_{0,1}^*)_{\uparrow}. \end{aligned}$$

- Example: uu , $\Gamma = 1$ (repulsive, medium asymptotic value),

$$\begin{aligned} & (C1)_{AB} \left(\bar{Q}_C(-\mathbf{r}/2)q_A^{(u)}(-\mathbf{r}/2) \right) \left(\bar{Q}_D(+\mathbf{r}/2)q_B^{(u)}(+\mathbf{r}/2) \right) \propto \\ & \propto (B^{(*)})_{\uparrow}(B_{0,1}^*)_{\downarrow} - (B^{(*)})_{\downarrow}(B_{0,1}^*)_{\uparrow} + (B_{0,1}^*)_{\uparrow}(B^{(*)})_{\downarrow} - (B_{0,1}^*)_{\downarrow}(B^{(*)})_{\uparrow}. \end{aligned}$$

$\bar{b}\bar{b}qq$ / BB potentials (5)

Why are certain channels attractive and others repulsive? (1)

- Fermionic wave function must be antisymmetric (Pauli principle); in quantum field theory/QCD automatically realized.
- qq isospin: $I = 0$ antisymmetric, $I = 1$ symmetric.
- qq angular momentum/spin: $j = 0$ antisymmetric, $j = 1$ symmetric.
- qq color:
 - $(I = 0, j = 0)$ and $(I = 1, j = 1)$: must be antisymmetric, i.e., a triplet $\bar{3}$.
 - $(I = 0, j = 1)$ and $(I = 1, j = 0)$: must be symmetric, i.e., a sextet 6 .
- The four quarks $\bar{b}\bar{b}qq$ must form a color singlet:
 - qq in a color triplet $\bar{3}$ → static quarks $\bar{b}\bar{b}$ also in a triplet 3 .
 - qq in a color sextet 6 → static quarks $\bar{b}\bar{b}$ also in a sextet $\bar{6}$.

$\bar{b}\bar{b}qq$ / BB potentials (6)

Why are certain channels attractive and others repulsive? (2)

- Assumption: attractive/repulsive behavior of $\bar{b}\bar{b}$ at small separations r is mainly due to 1-gluon exchange,
 - color triplet $\bar{3}$ is attractive, $V_{\bar{b}\bar{b}}(r) = -2\alpha_s/3r$,
 - color sextet $\bar{6}$ is repulsive, $V_{\bar{b}\bar{b}}(r) = +\alpha_s/3r$

(easy to calculate in LO perturbation theory).

- Summary:

- $(I = 0, j = 0)$ and $(I = 1, j = 1)$ → attractive $\bar{b}\bar{b}$ potential $V_{\bar{b}\bar{b}}(r)$.
- $(I = 0, j = 1)$ and $(I = 1, j = 0)$ → repulsive $\bar{b}\bar{b}$ potential $V_{\bar{b}\bar{b}}(r)$.

- Expectation consistent with the obtained lattice results.
- Pauli principle and assuming “1-gluon exchange” at small r explains, why certain channels are attractive and others repulsive.

$\bar{b}\bar{b}qq$ / BB potentials (7)

- Summary of $\bar{b}\bar{b}qq$ / BB potentials:

$B^{(*)}B^{(*)}$ potentials:	attractive:	$1 \oplus 3 \oplus 6$	(10 states).
	repulsive:	$1 \oplus 3 \oplus 2$	(6 states).
$B^{(*)}B_{0,1}^*$ potentials:	attractive:	$1 \oplus 1 \oplus 3 \oplus 3 \oplus 2 \oplus 6$	(16 states).
	repulsive:	$1 \oplus 1 \oplus 3 \oplus 3 \oplus 2 \oplus 6$	(16 states).
$B_{0,1}^*B_{0,1}^*$ potentials:	attractive:	$1 \oplus 3 \oplus 6$	(10 states).
	repulsive:	$1 \oplus 3 \oplus 2$	(6 states).

- 2-fold degeneracy due to spin $j_z = \pm 1$.
- 3-fold degeneracy due to isospin $I = 1, I_z = -1, 0, +1$.

→ 24 **different** $\bar{b}\bar{b}qq$ / BB potentials.

$\bar{b}\bar{b}qq$ / BB potentials (8)

- Focus on the two attractive channels between B and B^* :
 - Scalar isosinglet ($(I = 0, j = 0)$, more attractive):
 $qq = (ud - du)/\sqrt{2}$, $\Gamma = (1 + \gamma_0)\gamma_5$.
 - Vector isotriplet ($(I = 1, j = 1)$, less attractive):
 $qq \in \{uu, (ud + du)/\sqrt{2}, dd\}$, $\Gamma = (1 + \gamma_0)\gamma_j$.
- Computations for $qq = ll, ss, cc$ ($l \in \{u, d\}$) to study the mass dependence.
- Parameterize lattice potential results by continuous functions obtained by χ^2 minimizing fits of

$$V_{\bar{b}\bar{b}}(r) = -\frac{\alpha}{r} \exp\left(-\left(\frac{r}{d}\right)^p\right) + V_0 :$$

- $1/r$: 1-gluon exchange at small $\bar{b}\bar{b}$ separations.
- $\exp(-(r/d)^p)$: color screening at large $\bar{b}\bar{b}$ separations due to meson formation.
- Fit parameters α , d and V_0 ; $p = 2$ from quark models.

$\bar{b}\bar{b}qq$ / BB potentials (9)

- Potentials for $qq = ll$, $l \in \{u, d\}$ are wider and deeper than potentials for $qq = ss, cc$.
 → **Good candidates to find tetraquarks are systems of two very heavy and two very light quarks, i.e., $\bar{b}\bar{b}ll$.**

$\bar{b}\bar{b}qq$ tetraquarks (1)

- Solve the Schrödinger equation for the relative coordinate of the heavy quarks $\bar{b}\bar{b}$ using the previously computed $\bar{b}\bar{b}qq / BB$ potentials,

$$\left(-\frac{1}{2\mu}\Delta + V_{\bar{b}\bar{b}}(r) \right) \psi(\mathbf{r}) = E\psi(\mathbf{r}) \quad , \quad \mu = m_b/2.$$

- Possibly existing bound states, i.e., $E < 0$, indicate stable $\bar{b}\bar{b}qq$ tetraquarks.
- There is a bound state for $qq = (ud - du)/\sqrt{2}$ (i.e., the scalar isosinglet potential) and orbital angular momentum $l = 0$ of $\bar{b}\bar{b}$, binding energy $E = -90^{+43}_{-36}$ MeV with respect to the $B + B^*$ threshold, i.e. confidence level $\approx 2\sigma$.
- No further bound states, in particular not for $qq = ss, cc$ (i.e., $B_s B_s, B_c B_c$).

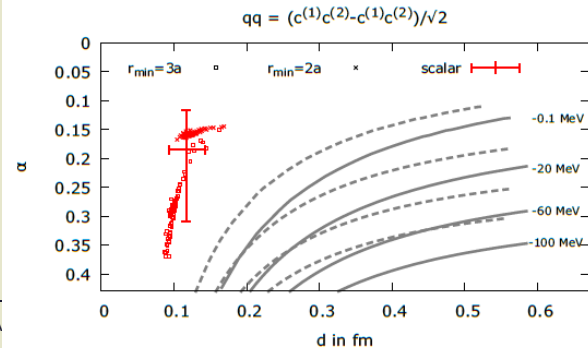

$\bar{b}\bar{b}qq$ tetraquarks (2)

- Estimate the systematic error by varying input parameters:

- the t fitting range to extract the potential from effective masses,
- the r fitting range for

$$V_{\bar{b}\bar{b}}(r) = -\frac{\alpha}{r} \exp\left(-\left(\frac{r}{d}\right)^p\right) + V_0.$$

- Right: isoline plots of the binding energy E for $l = 0$.
- Bottom: histogram for the binding energy E for $qq = (ud - du)/\sqrt{2}$ and $l = 0$.

$\bar{b}\bar{b}qq$ tetraquarks (3)

- To quantify “no binding”, we list for each channel the factor, by which the reduced mass μ in the Schrödinger equation has to be multiplied, to obtain a tiny but negative energy E (again for $l = 0$).

qq	spin	factor
$(ud - du)/\sqrt{2}$	scalar	0.46
$uu, (ud + du)/\sqrt{2}, dd$	vector	1.49
$(s^{(1)}s^{(2)} - s^{(2)}s^{(1)})/\sqrt{2}$	scalar	1.20
ss	vector	2.01
$(c^{(1)}c^{(2)} - c^{(2)}c^{(1)})/\sqrt{2}$	scalar	2.57

- Factors $\ll 1$ indicate strongly bound states, while for values $\gg 1$ bound states are essentially excluded.
- Light quarks (u/d) are unphysically heavy (correspond to $m_\pi \approx 340$ MeV); physically light u/d quarks yield similar results.
- Mass splitting $m(B^*) - m(B) \approx 50$ MeV, neglected at the moment, is expected to weaken binding (will be discussed below).

$\bar{b}\bar{b}qq$ tetraquarks (4)

What are the quantum numbers of the predicted $\bar{b}\bar{b}qq$ tetraquark?

- $I(J^P) = 0(1^+)$.

- Light scalar isosinglet: $qq = (ud - du)/\sqrt{2}$, $I = 0$, $j = 0$ in a color $\bar{3}$, $\bar{b}\bar{b}$ in a color 3 (antisymmetric) ... as discussed above.
- Wave function of $\bar{b}\bar{b}$ must also be antisymmetric (Pauli principle).
 - * $\bar{b}\bar{b}$ is flavor symmetric.
 - * $\bar{b}\bar{b}$ spin must also be symmetric, i.e., $j_b = 1$.
- **The predicted $\bar{b}\bar{b}qq$ tetraquark has isospin $I = 0$, spin $J = 1$.**
- We study a state, which correspond for large $\bar{b}\bar{b}$ separations to a pair of $B^{(*)}$ mesons in a spatially symmetric s-wave.
- **The predicted $\bar{b}\bar{b}qq$ tetraquark has parity $P = +$** (the product of the parity quantum numbers of the two mesons, which are both negative).

Inclusion of heavy spin effects

- Heavy spin effects have been neglected so far, e.g. mass splitting $m_{B^*} - m_B \approx 46$ MeV.
- Mass splitting $m_{B^*} - m_B$ is, however, of the same order of magnitude as the previously obtained binding energy $E = -90_{-36}^{+43}$ MeV.
- Moreover, two competing effects:
 - The attractive $\bar{b}b u d$ channel corresponds to a linear combination of BB^* and/or B^*B^* .
 - The BB^* interaction is a superposition of attractive and repulsive $\bar{b}b u d$ potentials.
- Will there still be a bound state, when heavy spin effects are taken into account?
 - Yes.
 - We include heavy spin effects by solving a coupled channel Schrödinger equation. [P. Bicudo, J. Scheunert, M.W., Phys. Rev. D **95**, 034502 (2017) [arXiv:1612.02758]]
 - Binding energy $E = -59_{-30}^{+38}$ MeV.
 - Tetraquark is approximately a 50%/50% superposition of BB^* and B^*B^* (strong attraction more important than light constituents).

$\bar{b}b\bar{q}q$ / $\bar{B}B$ potentials

- Exploring the existence of $\bar{b}b\bar{q}q$ tetraquarks in the same way is more difficult:
 - $\bar{b}bqq$ (discussed on previous slides) can decay into:
 - * $\bar{B} + \bar{B}$.
“Easy” ... on the level of the Schrödinger equation for the relative coordinate of the two \bar{b} quarks (step (2) of the BO approximation).
 - $\bar{b}b\bar{q}q$ can decay into:
 - * $\bar{B} + B$.
“Easy” ... on the level of the Schrödinger equation for the relative coordinate of the \bar{b} quark and the b quark (step (2) of the BO approximation).
 - * $\bar{b}b + \bar{q}q$ (“bottomonium + pion”).
“Rather hard” ... on the level of lattice QCD, when computing the $\bar{b}b$ potentials in the presence of $\bar{q}q$ (step (1) of the BO approximation).
 - A potential can be relevant for a $\bar{b}b\bar{q}q$ tetraquark (if $\bar{q}q$ is close to $\bar{b}b$) ...
 - ... or just a $\bar{b}b$ potential shifted by the mass of a $\bar{q}q$ meson.
- Work in progress.
 - [A. Peters, P. Bicudo, L. Leskovec, S. Meinel and M.W., PoS LATTICE 2016, 104 (2016) [arXiv:1609.00181]]
 - [A. Peters, P. Bicudo and M.W., EPJ Web Conf. 175, 14018 (2018) [arXiv:1709.03306]]

Summary and outlook

- Computation of 3×24 different $\bar{b}bqq / BB$ potentials.
 - Factor 3: quark mass, $u/d, s, c$.
 - Factor 24: $(I, I_z, |j_z|, P, P_x)$.
- Prediction of a stable $\bar{b}bqq, qq = (ud - du)/\sqrt{2}$ tetraquark.
 - Quantum numbers $I(J^P) = 0(1^+)$.
 - Binding energy $E = -59_{-30}^{+38}$ MeV with respect to the $B + B^*$ threshold.
- $\bar{b}bqq / BB$ potentials allow investigation of $\bar{b}bqq$ tetraquark resonances.
 - Next talk be Pedro Bicudo.
- Future plans:
 - Explore $\bar{b}bqq$ tetraquark resonances in detail.
 - Investigate the structure of the predicted $I(J^P) = 0(1^+)$ tetraquark ... is it a mesonic molecule or rather a diquark-antidiquark?
 - Study $\bar{b}b\bar{q}q / BB$, which is experimentally more relevant ($Z_b(10610)^+, Z_b(10650)^+, \dots$), but theoretically much harder.
